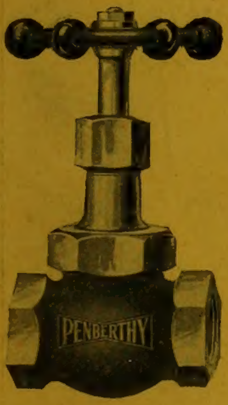
TRADE PENBERTHY MARK



Regrinding Brass Valves
"THE ALL QUALITY LINE"
The Finest Valve on the Market

Some Sound Practical Reasons Why the Penberthy Valve is Superior

The bonnet is secured to body by heavy union ring, and the threads on bonnet end of body being on outside makes the above connection rigid, steam tight and non-corrosive, and permits free accessibility to valve at any time without strain or injury to same.

The regrinding feature of the Penberthy Valve with metal to metal seats, is much superior to, and more economical than, the composition disc valve, which type is only recommended for ordinary steam pressure and which necessitates the frequent renewing of discs at extra expense.

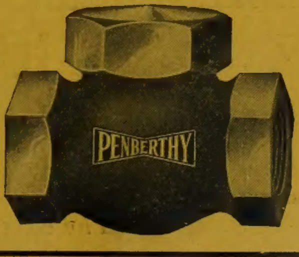
The regrinding feature of the Penberthy Valve entirely eliminates the necessity of renewing discs and permits both the seat of body and seat of disc to be reground together quickly and with no extra expense.

The metal is of the best quality and is so distributed that the parts subjected to the greatest strain and wear have proportionately heavier walls.

The design, workmanship and finish is not equalled by any other valve on the market.

"Specify Penberthy Regrinding Valves"

They will add to and increase the efficiency, economy and prosperity of every building or power plant in which they are installed.



Approved by and Registered in Ontario and the Western Provinces for Steam Pressures as high as 200 lbs.

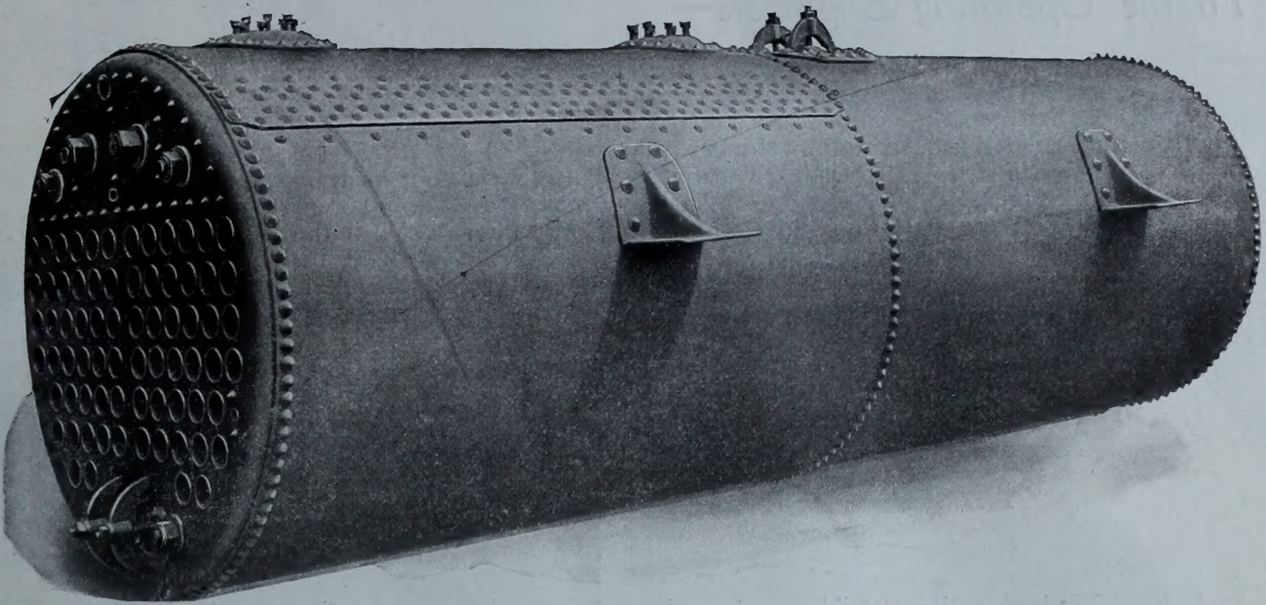
FOR SALE EVERYWHERE



Waterous Boilers

For Power and Heating Purposes

If you want **boiler service** and **boiler satisfaction** in your power plant, install WATEROUS HORIZONTAL TUBULAR BOILERS.

They are economical of fuel—carry a big reserve steam pressure for use in emergencies—can be used with hard and dirty water and they are easily cleaned and taken care of.

We build them in sizes from 40" x 10' to 72" x 18' for all Provinces. If we cannot supply you at once from stock we can turn out your order in quick time.

Waterous Boilers cost little new—up-keep expenses are practically negligible. Let us quote prices and delivery on the next one you buy.

All the Steam
You Want—
All the Time

The Waterous Engine Works Co., Limited

BRANTFORD, CANADA

To the Operating Engineers—

We want to thank you very heartily for the support that you have given the Dunham goods during the year just closed.

It has been the aim of this Company to make the very best Radiator Trap that modern genius, labor and machinery can produce. A trap that would eliminate the numerous troubles experienced in some vacuum systems of heating. A trap which will be accepted by the engineers strictly upon its merits, because you are the men who use these specialties and are in a position to know which is the best.

The unanimous expression of satisfaction with the Dunham Trap from Operating Engineers over Canada, strongly indicates that the Dunham Trap is doing what we claim for it and that it makes intimate and lasting friends with the engineers who have taken the trouble to use it.

We want your liberal support during the new year of 1914, and we promise to give you better Dunham Traps than ever before, and you will, by using Dunham Traps, fill several Cups of Joy and Happiness to overflowing.

Your Own. By eliminating troubles and complaints from unsatisfactory heating systems.
Your Boss. By saving many dollars from the coal-pile through economy of the Dunham System.
Ourselves. By adding to our circle of friends, profitable and satisfied customers.

We have a liberal trial offer to make you, whereby you may become the better acquainted with the Dunham Trap. Write us.

Yours for better service in consideration of your business, we are,

Yours very truly,

C. A. DUNHAM CO., Ltd., TORONTO, ONT.

Interior view of Cochrane Multiport Safety Exhaust Outlet Valve (vertical type)

REMEMBER THE WORD

"MULTIPORT"

WHEN YOU WANT A FIRST-CLASS BACK PRESSURE VALVE

The Cochrane Multiport Safety Exhaust Outlet Valve is called a "Multiport" because it contains several small disks instead of one large disk, each fitted with its own independent spring and dash pot.

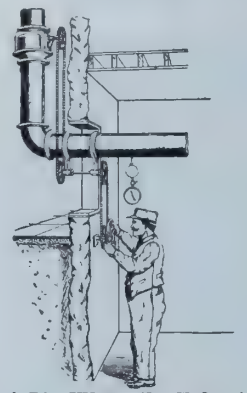
There are several reasons for having a number of disks instead of one.

(a) The chances of all disks becoming jammed or stuck at once is infinitesimal.

(b) The small disks are lighter and require less travel, hence less hammering of the valve face and seat.

(c) Small valves are less liable to leak, and are more easily ground to their seats.

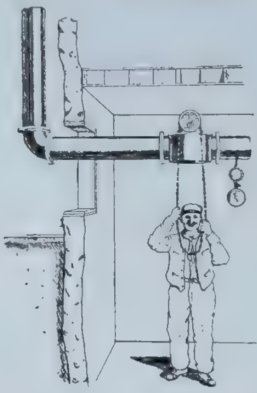
(d) The small disks are easily removable through hand-holes in the casing.



A Good Rig Where the Valve is Outdoors or at a distance.

With the Cochrane Multiport **you can easily modify the back-pressure** as required to meet the heating requirements at different periods during the day, by raising or lowering the pressure plate which bears upon the springs, holding the disks to their seats. This pressure plate is operated by a hand-wheel on the outside of the casing, or from a distance, by means of chains, rods, hydraulic pressure, electric motor, etc.

Cochrane Multiports are made not only for back-pressure service, but also for vacuum service to protect condensers, in which case the disks are water-sealed.



Showing What a Snap It Is to Change the Back Pressure with a Cochrane Multiport.

The Cochrane Flow Valve is indispensable wherever mixed-flow turbines are installed, in order to prevent vacuum from the turbine casing backing up into the engine exhaust line and drawing in air through leaks and through piston rod and valve-stem packings. Where bleeder turbines are installed, a Cochrane Multiport should be used as a check valve to prevent live steam, which may be supplemented to the low-pressure steam-utilizing system, from flowing back into the turbine and overspeeding the latter during periods of light load.

For the latest ideas on back pressure valves, also information on the effect of back pressure on steam consumption of engines, send for our booklet, "The Evolution of the Cochrane Multiport," No. 15-V.

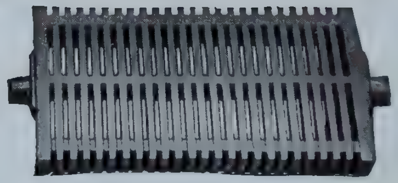
"THE Cyclone"

Shaking and Dumping Grate Bar



Efficiency

demands that you burn your fuel as completely as possible, that you convert a high percentage of the heat units contained in the coal into useful work.

The "Cyclone" because of the large draught area it gives—over 60% of grate area—because the shaking mechanism allows the fire to be kept clean and bright and the bars free from clinkers, burns any fuel in such a manner as to produce the highest thermal efficiency possible with that particular grade.

And the positive locking mechanism keeps the bars firmly in place, yet allows of their being readily agitated or the fire easily dumped.

Next time your boiler needs a new set of bars install a "Cyclone" Grate, and see what a big slice in the coal bill the "Cyclone" will make. But, be sure you specify the "Cyclone" and get the "Cyclone," as we are constantly being flattered by being imitated.

So now—before you forget it—drop us a line, and let us tell you what some of its users have to say.

Stop Blow-outs and Leaks in Pipe Lines by Using

GOETZE No. 2 ELASTIC GASKETS

If you start right now to renew with No. 2 ELASTIC GASKETS, you can steadily reduce your renewals until you have brought them almost to the vanishing point.

This is not a mere "claim"—it is backed up by a *guarantee*—in fact the strongest guarantee ever made by a gasket manufacturer.

Think what it means to re-gasket a joint so it will *keep tight for years,* instead of days or weeks. Think of the saving resulting in gasket costs, labor and shut-downs.

What No. 2 Elastic Gaskets Will Do

No. 2 Elastic Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight. Prevent leaks, blow outs and shut-downs. Will practically eliminate renewal expense for gaskets.

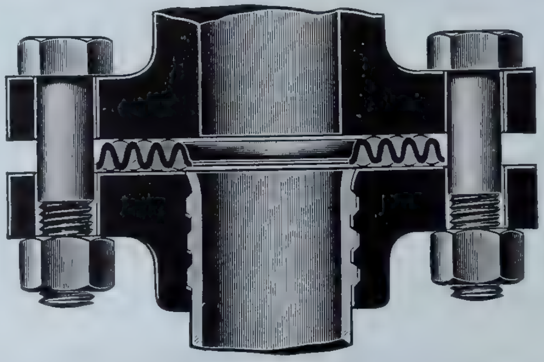
No. 2 Elastic Gaskets are for high pressure and super-heated steam lines, but owing to their indestructible nature, are equally adapted to *any and every condition* about a factory, mill or refinery.

The No. 2 Elastic Guaranteed

Every No. 2 Elastic Gasket is Guaranteed for 5 Years' Continual Service in the Same Joint

There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every No. 2 Gasket whether bought direct from us or through a dealer.

How No. 2 Elastic Gaskets are Made



These Gaskets are made of corrugated copper with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.

Goetze Gaskets are carried in stock by

P

It is the same Old Game

For the "victim" the result is always the same, whether he gamble on the "shell game" or on imitations of the REAL Daniel's P. P. P. Rod Packing.

The engineer who takes a "chance" on imitations of P. P. P. makes a whole lot of trouble for himself; the bother of a "blowing," leaking engine and its frequent repacking at night or on Sundays. The dealer, as a rule, knows little about the practical values of packings and, naturally, sells the kinds that offer the largest and most frequent profits.

Neither the engineer who buys the substitutes for P. P. P. or the dealer who sells them is dishonest—they simply do not know what experience would show them; that the GENUINE P. P. P. gives the longest service and saves hundreds of dollars, yearly, on the coal pile.

DANIEL'S ROD PACKING

P. P. P.

COIL, SPIRAL, RING

Daniel's is the ORIGINAL "sliding-wedge" and "compressible-cushion" packing, and is the only one whose claims are backed with SCIENTIFIC PROOF.

Others may copy the form of P. P. P. or follow our advertising, BUT P. P. P. is the only one that does what we PROVE P. P. P. does.

Insist on getting the box with the big RED D (see illustration) and the signature of C. A. Daniel.

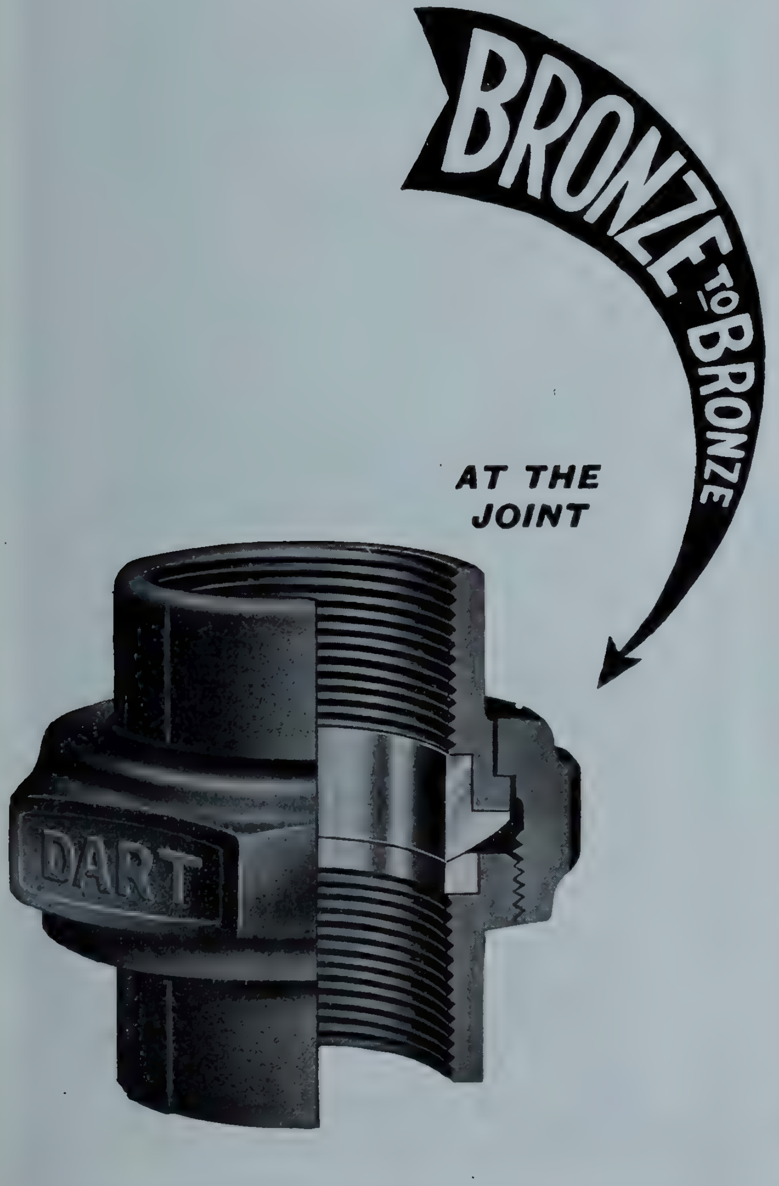
Make Permanently Tight Joints



Have Heavy Iron Parts that Cannot Stretch or Pull Apart.

Bronze on Each Face of the Joint Makes Corrosion Impossible.

The bronze to bronze ball-shaped seat of the Dart Union allows for a perfect and **practically everlasting joint** between pipes, whether they are in or out of line.

All that is necessary is to draw the two faces together and you have a joint that defies time, pressure, corrosion, vibration, expansion and contraction, yet may be easily unjointed and jointed as often as you wish.

All Dart Unions have the trade-mark as shown on the cut. We will promptly replace two for one any Dart Union that is found defective.

Jobbers from coast to coast sell them.

DART UNION CO., LTD., TORONTO

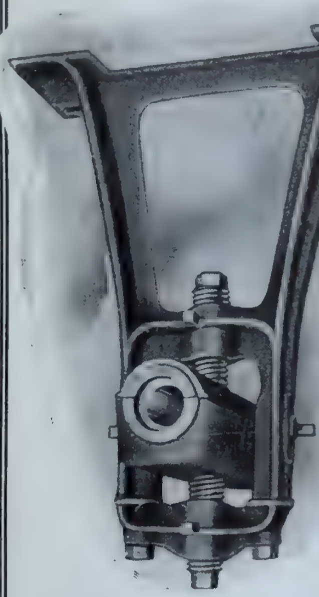
ELMIRA

Ball & Socket HANGERS

For MAXIMUM Service

Wood Split PULLEY

AND BIG REDUCTION IN POWER TRANSMISSION COST



The "Elmira" Ball and Socket Hanger

is exceptionally strong and heavy. In this hanger a union system of oiling is employed, a combination of centrifugal and capillary attraction, effected by tempered steel rings and woven cotton distribution of lubricant, and precludes the slightest possibility of "Dry Bearings" so long as any oil remains in the reservoir or dry chamber, one filling of which should last from six to twelve months.

The "Elmira" Wood Split Pulley

You can use an "Elmira" Pulley any place that a leather belt will give satisfaction, and know that what any good pulley will do, it will do, and more.

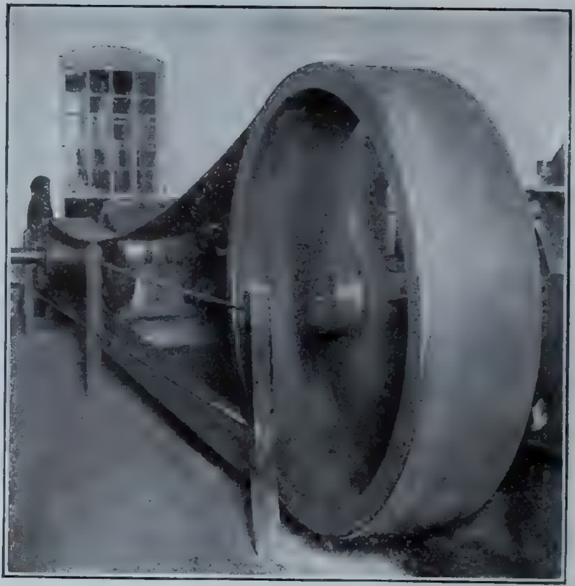
This pulley stands the hardest and most severe conditions. It is nailed throughout. The arms are tenoned into rim and dowelled there.

Absolutely guaranteed.

It will be much to your interest to let us furnish you with our illustrated catalog. Write for it to-day.

Large and complete stocks carried at Elmira and by The A. M. Ellicott Co., 301 St. James Street, Montreal, Que., Sole Eastern Agents.

Elmira Machinery & Transmission Co., Ltd.
ELMIRA, CANADA



The belt in this photograph is 3-ply;

it is transmitting 220 h.p.; is under a tension of over 1445 pounds on the pulling side;

and yet

THE TOP SIDE RUNS SLACK

Cling-Surface Does It

When this belt was photographed (in the plant of the Wilkes-Barre Light Co., Wilkes-Barre, Pa.), it was pulling 220 horse power. Looks as though it was pulling nothing, doesn't it? Increase the load to 268 h.p., the rated capacity of the generator, or even higher, and it will act equally well—makes no difference to a Cling-Surface-treated belt—the greater the load the further it lies down on the pulley and pulls, for it is the contact that counts. Treated with Cling-Surface a belt can't slip, especially if it is provided with a fairly liberal arc of pulley contact as above.

The belt isn't made the least bit sticky, but rendered pliable and slipless by the penetrating and lubricating action of Cling-Surface.

The speed of the above flywheel is 240 r.p.m. and its diameter is 80 inches. The generator is 200 kw., 3 phase, 2300 volt, 60 cycle, and its pulley is 32 inches in diameter. Distance between centres 24 feet. When the belt was new it was not treated for three months. It became oily and dirty and began slipping. Even the tightener would not prevent slip. Then Cling-Surface treatment began, and they write: "Followed Cling-Surface instructions on first application and since then gave an occasional application with brush. Result—no trouble whatever on account of belting." We have thousands of installations doing equally as well.

Send your trial order now. We quote f.o.b. Toronto.

Of Human Interest

There is often more to our advertisements than the mere dry, technical side. There is food for the imagination in such letters as the one we recently published from an Engineer in far-off fever-stricken Africa, where, like as not, he met, as he was going in, the coffin of his predecessor as it was coming out; or the letter from the Engineer describing his anxiety as he watched the crank pin of a racing engine in a gale off a lea shore in the Bay of Biscay. Below we give an interesting letter from Arica, Chili. These letters, coming from the remotest parts of the earth as well as many nearby, all gratefully acknowledge that Magnolia Metal stands up to the scratch where other babbitts go down, and its value is sometimes almost beyond computation.

FERROCARRIL LONGITUDINAL DE CHILE SECCION NORTE.
Contratistas, Macdonald, Gibbs & MacDougall (Chile)., Arica, 5 Apr., 1913.

Gentlemen:—I have great pleasure in stating to you the result of my experience in different classes of metal that I have tested on our engines here; which, considering the difficult work that I have to do, is pleasing. The great trouble on our rack loco engines was that the wear on the working parts was so much that they were continually in the shop; now, you can understand that on construction work to have your engines lying in the shop it was up to the shop, and the Manager saw it too. I tried babbitt true metal, solid brasses, other classes of metal, but not until I met your Magnolia did I get the relief that was my aim. On this road where the rain has not fallen for more than human agency can remember, the dust is so great that it almost beats the Sahara; and for your metal to show the road to other makers as regards economy in cost in wearing ability, therefore most reliable, is, I think, a splendid recommendation to other engineers who may be in need of a good metal, to whom reliability is everything.

Yours faithfully, (Signed) H. S. THOMAS, Engr.

PRACTICAL BOOKS FOR PRACTICAL MEN

These books were written especially for practical self-instruction, by experts whose experience and standing make them authorities.

They are so clear that the beginner can understand them; so thorough that the trained worker can learn from them; so practical that they will give any man a working knowledge of the subjects that they treat, and save him both time and money.

They not only cover the fundamental principles of mechanical science, engineering practice, and business usage, but also present the latest developments and the accepted practice of the most successful men, in those lines.

They give men a practical knowledge of practical things, which enables them to think more accurately and to work more efficiently; and they compose the most helpful, reliable, and comprehensive series of **home study** books ever put upon the market.

In an Age of Steel—
Steel is the Best
Pulley Material

WHEREVER strength combined with lightness is desired, whether in the skeletons of sky scrapers or in watch springs, steel is used. These same qualities make steel the logical pulley material.

"American"
Steel Split Pulleys

are probably more numerously used than any other make of metal pulley, and more than all other steel pulleys combined.

Of the more than 2,000,000 "American" Pulleys shipped from our factory, less than two-tenths of one per cent. have been reported as failing in service.

"American" Pulleys are light, strong and practically indestructible. They may be bushed down so as to take an immovable grip on various sizes of shafts.

Bowser Service Idea

From the foundation of the Company we have been governed by the "SERVICE IDEA." The public's discrimination, intelligence and appreciation of true values have not only been understood, but have been the chief force in shaping this business. Sound values are so adjusted to reasonable prices that there is bound to be a saving of money, true value considered.

The BOWSER was the first long distance, self-measuring oil storage equipment ever made. Twenty-eight years ago, S. F. Bowser, President of S. F. Bowser & Company, Inc., invented and patented the first BOWSER; built the first of the long line of BOWSER SYSTEMS that have meant so much to every individual, firm and dealer having occasion to store oil of any kind.

To-day the Company occupies over 8 acres of floor space, employs nearly 1,000 men in the factory the year round, has over 450 specialty salesmen on the road, 200 or more in the office and its equipment is sold through Branch Offices located in almost all foreign countries.

Bowser Equipment is an Investment

for the far-seeing man who is looking for big, though sure, returns on his outlay. It is a dividend producer rather than a yearly depreciating fixture. It is an insurance policy with only one premium—it soon begins to pay premium.

It means a system which will properly store and accurately distribute the liquids in any plant, whether it be large or small.

It means lower production costs and economy from every standpoint.

It means increased working capacity and all-round satisfaction in the beginning as well as in the ultimate.

Is it any wonder that there are to-day over a million satisfied users in every class of business who daily testify by their enthusiastic use of Bowser equipment what BOWSER SERVICE has done for them?

Is it not reasonable to suppose that this Company's Success must be founded upon Satisfactory Service, otherwise it would have failed soon after it started.

An inquiry costs little, does not obligate you in the least and may be the means of saving you and your stockholders many dollars now unknowingly wasted.

How to Charge Furnaces Economically

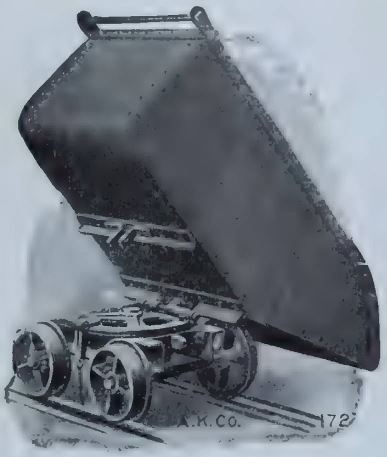
A very important factor in the problem of keeping a constant supply of power is that of how to stoke furnaces efficiently. We are selling agents for a system of conveying coal and for charging furnaces in boiler rooms which requires very little labor and is practically indestructible. This system consists of the well known Koppel Cast Plate Track and Charging Cars.

ORENSTEIN-ARTHUR KOPPEL

Coal Charging Cars for the conveying of coal to boiler rooms are made of steel and are very durable. They are light in weight and easy and convenient to operate, being designed with special reference to boiler room service. The height of the cars is such as to make shoveling very convenient for the stoker. They may be supplied either with two side doors or end doors, as desired, and with or without swiveling base.

The rails of the track used in our boiler room systems are cast integrally with solid sectional plates, which provide a level surface to walk upon while car is being propelled.

We have a very interesting catalogue on this subject, showing many installations of the Koppel System, together with illustrations of cars, track, switches, turntables, etc., which we should like to send you. Ask for catalogue 412.



A VERY satisfactory type of car for use in hauling ashes, dirt, etc., is the Scoop Car, which can be dumped either between the rails or to either side. Standard capacities are 12, 18 or 27 cubic feet for gauges of 18 or 24 inches.

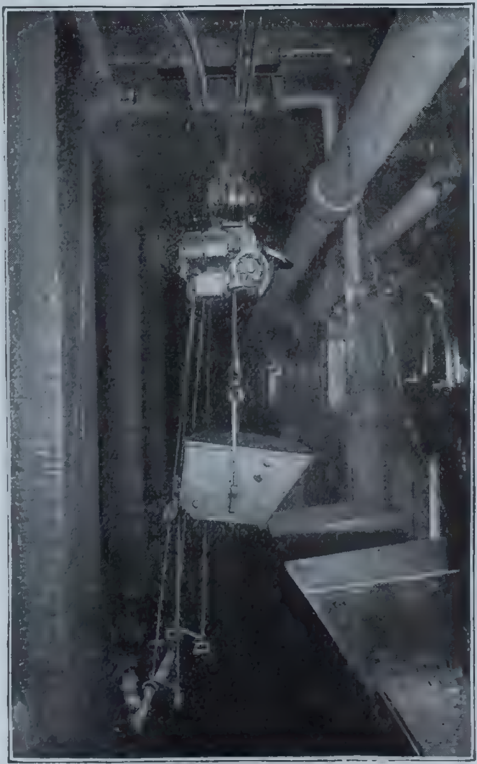
THE TRIPLEX BLOCK



The Best Practice in Power Plants

THE new book of Hoists shows modern boiler room installation for handling coal by electric hoist and trolley. Under 4,000 lb. loads these hoists travel 350 feet per minute from bunkers to furnace, controlled from the floor or from a trailer cage.

Both for the Power Plant or Marine Engineer this book shows the latest application of chain blocks and trolleys to enable one man to lift, move and adjust any load up to 20,000 pounds.

Write for a copy of this book to-day. It will result in decreased costs in handling.

Safety of Steel

The Triplex Block is steel construction—steel in all load bearing parts, sheave, gears, pinion, hooks and chain.

This Hose Won't Kink or Collapse

J-M Flexible Metallic Hose cannot be bent at sharp angles because the spirals "butt" on the inside curve (see illustration). This makes *kinking* impossible. Yet the hose is sufficiently flexible to meet *every practical service requirement.*

Unlike ordinary hose, it will not break through in spots, blow out or quickly disintegrate. It resists a direct end pull of 1000 to 3000 lbs., and a crushing strain of 300 to 800 lbs., to each four turns of its armor, according to the diameter of the hose.

J-M Flexible Metallic Combination Hose

TWO HOSE IN ONE

consists of a light-weight inner lining of high-grade rubber hose protected by a continuous interlocking metal armor. It is absolutely pressure-tight under all conditions and can't be put out of service unless both the inner tube and outer protecting armor are cut through and through.

The great economy of this hose lies in the fact that when the inner tube becomes worn out it can be renewed at a very small cost. The metallic armor will outwear many inner tubes.

Our Booklet describes in detail other advantages and economies of this hose. Write nearest Branch for a copy.

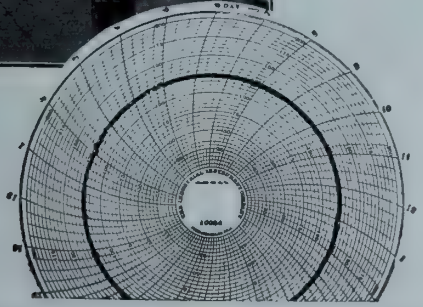
BUFFALO, N. Y.

You can do it in Your Plant, too

You can get complete combustion and a smokeless stack—you can get a steady steam pressure, regardless of your loads —you can burn less coal, and cheaper coal— AFTER you instal a



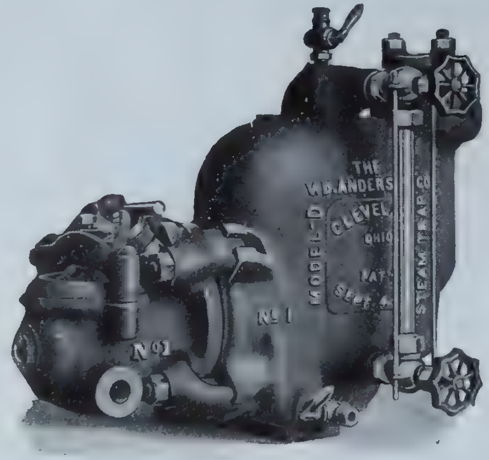
JONES UNDERFEED STOKER

What the Jones Stoker is doing in this plant at London, Ont., and what it is doing in hundreds of other plants, it will do in yours.

JONES UNDERFEED STOKER CO., LIMITED

NATIONAL TRUST BUILDING - TORONTO

The Trap for every place—



On that 120 lb. main—to protect the engine; on those 60 lb. coils in the vacuum pass; on those big exhaust heaters under the drying ovens. Anywhere, everywhere where there's condensation to handle put an

Anderson
Model "D" Steam Trap

And its unique construction allows you to use the **same trap** in any of those places, merely changing valve and seat to adopt it for varying pressures.

Doesn't this spell "trap economy?" Doesn't it appeal to you who have so many condensation problems to solve?

Rugged in construction, built interchangeably, making no mistakes, the Anderson will take care of your steam-mains with ever-watchful regularity.

You cannot afford to tolerate a trap that's inefficient, that either doesn't drain or else lets live steam through.

So get our booklet—it describes the Anderson.

The V. D. Anderson Co.

West 96th St., Cleveland, Ohio

BRANCH OFFICES: 330 Manhattan Building, Chicago, Ill.; 6047 Jenkins Arcade, Pittsburg, Pa.; 3 Arch St., Philadelphia, Pa.; 212 Walnut St., Cincinnati, Ohio; 207 Union Trust Bldg., Baltimore, Md.; 91 High Street, Boston, Mass.

Upward Filtration

The filter bed of an open feed water heater makes a big difference in purity of feed water and care of the heater.

With the upward filtration in the

NATIONAL

DIRECT CONTACT FEED WATER HEATER AND PURIFIER

the impurities which do not settle in the sediment chamber are caught on the **under** side of the filter material.

The filter bed is relieved of all unnecessary work. It doesn't need cleaning as often. The filter material lasts longer and is more efficient while it is in use. Should the perforated supporting plates break and fall, the filter material will not be carried over to the pump, as would be the case in downward filtration.

The National is easy to care for—by means of the quick-opening blow-off valve a reverse current may be sent through the filter bed, thoroughly washing it.

Something New in Gauge Glasses

Stands 465 lbs.

The Test

"Resisto" and other Gauge Glasses were tested against hot pressure when suddenly brought into contact with cold water with the following results:

French Tubes broke at 90 lbs.
Scotch Tubes broke at 105 lbs.
Compound Tubes broke at 225 lbs.
Durax Tubes broke at 405 lbs.
RESISTO Tubes broke at 465 lbs.

THE "Resisto" Gauge Glass is the result of extensive study and experimenting for a **better** Gauge Glass.

Produced by the makers of the "Durax" Glass, the new "Resisto" has supplanted this famous glass. For the "Resisto" is even superior to the "Durax" in every requisite of an ideal Gauge Glass.

Send for pamphlet and free samples of the Resisto Gauge Glass.

Every genuine "Resisto" Glass has a red line through its center.

Unusually heavy gray horn fiber shell.

Short, active length of element assures uniform performance.

Links are attached to blade member by heavy machine screws.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

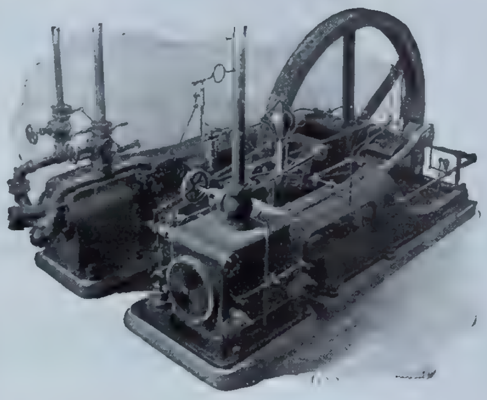
When Buying Refrigerating Machinery Better Be SURE Than SORRY



Some Ice Making and Refrigerating Plants are failures, not by reason of any inherent defects in the Machine or Apparatus, but because the type of Plant installed is not suited to meet existing conditions.

A Refrigerating Plant erected several years ago was found to be incapable of performing the duty required of it. Being given an opportunity to confer with the owners, we recommended a Plant of a different type, which was installed, and now the work is being done with ease, and at a considerable saving in water and fuel consumption.

This is not a knock. It's a boost. Every unsuccessful Plant is a detriment to the trade in general. A little care exercised in the beginning may prevent a bad investment—it is better to be Sure than Sorry! Our complete line enables us to make recommendations without prejudice. Why not safeguard your interests by giving us an opportunity to estimate on your requirements? Costs you nothing—may save you time and money.

We are ready and willing to confer with you on this important subject if you will but give us the opportunity.

Write us to-day.

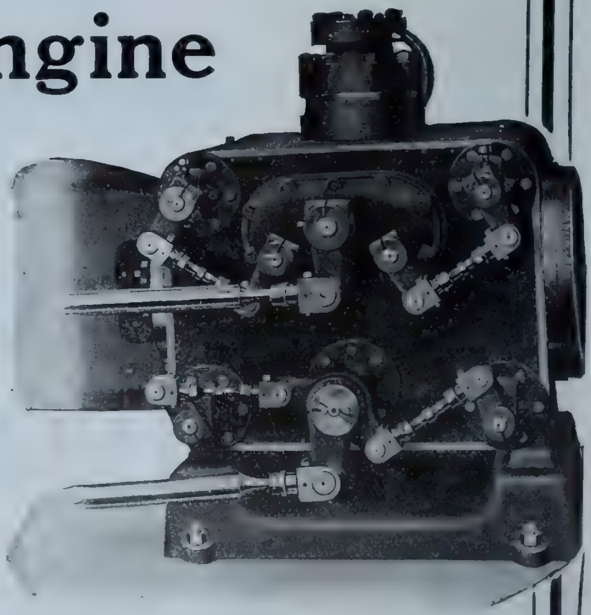
Corliss Economy and High Speed

Here's an engine which will save you fuel, for it's a Corliss. It runs at high speed—225 revolutions per minute—and the valve gear has only about one-half as many parts as the ordinary Corliss gear.

With a

Robb Corliss Engine



you don't have to sacrifice fuel saving for high speed. You don't have to get a slide valve engine for simplicity, or a vertical engine to save floor space. This engine combines Corliss saving with high speed and simplicity.

The valve gear has no springs, no latches, no cams, no disengaging parts. Multiported Corliss Valves permit small clearances, and use the steam almost perfectly.

Both single cylinder and compound.

Why The Advertiser Succeeds.

¶ Why is it that during the last few months, when money was admittedly tight, the manufacturers who advertised the most felt the pinch the least?

¶ And how is it that now, when the circulation of money is less restricted, the manufacturers who felt the pinch the most will be the last to experience relaxation and relief?

¶ The same wisdom and foresight which prompts a manufacturer to advertise will naturally guide him in forming his whole selling and general business policy, and, like a good general, he is prepared for every contingency and emergency.

¶ The fact that the successful business men is an advertiser is usually incidental. He is an advertiser because he is wise and possessed of good sound business sense and an analytical mind. At some time or other he came to the conclusion that advertising could be made one of the mightiest factors of his business organization, and having arrived at this conclusion, he just naturally went to it and advertised.

¶ He had faith in his product, and his own faith manifested in a public way, inspired confidence in the minds of his prospective customers. His name and his manufactured product became synonymous with good service and satisfying quality. The public became acquainted with the merits of his line and familiar with its outstanding features.

¶ Consequently, when conditions were normal, he secured a liberal share of business and received first consideration when purchases were made.

¶ When money tightened and business was curtailed, he continued to get the lion's share of what was going. When purchases were carefully considered the advertised line received first attention and usually secured the order.

¶ And now that the financial tide is coming back, the advertiser is getting the biggest slice of the business melon, simply because during those cloudy days of curtailment, his advertising message had been studied and absorbed at a time when the public mind was most receptive.

¶ It pays to advertise if your line is good, and it pays to buy advertised lines, because they are invariably satisfactory. The general public have long been educated to believe that advertised goods are best. Can't you see that you are laboring, not only under a handicap, but under a cloud, if your product is not advertised? Publicity dispels the cloud of suspicion and removes the handicap.

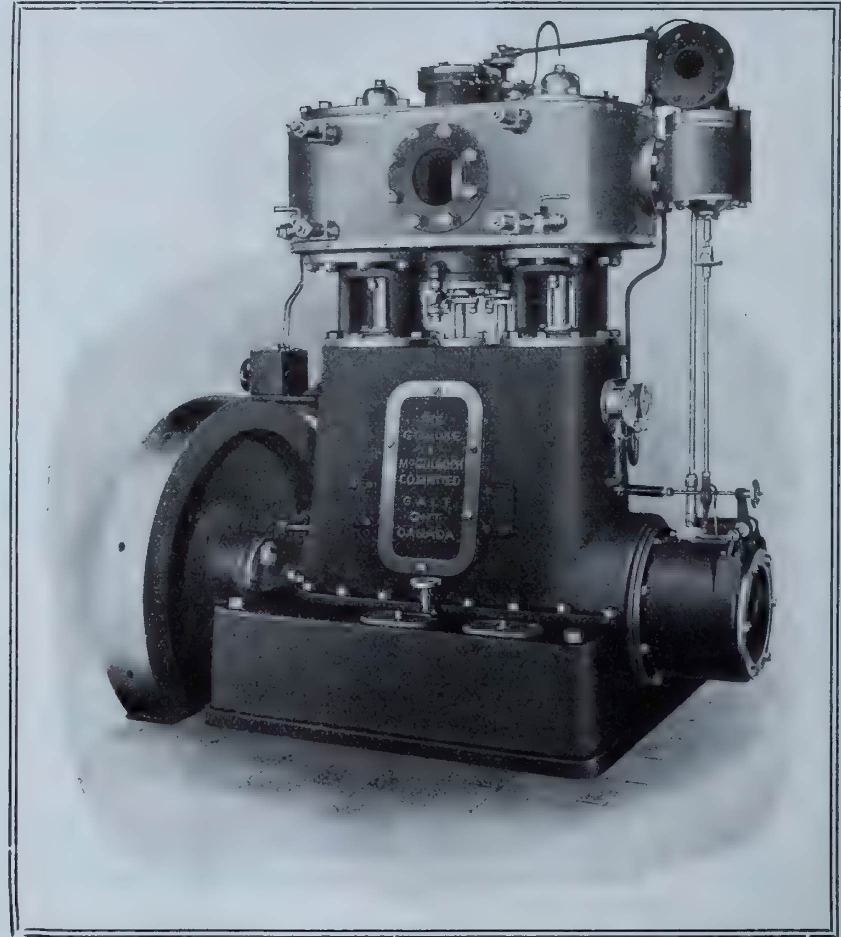
¶ You'd better hop on to the band wagon right away. Hopping on now, when the prospects for big business are so bright, will be not only timely, but extremely profitable.

G. & McC. VERTICAL QUICK REVOLUTION STEAM ENGINES

Will give you as they are giving others wherever installed

A MAXIMUM OF SERVICE

At a Minimum Cost of Upkeep



These Engines have a Perfect System of forced Lubrication.

They require little or no attention while running.

Built in all types and sizes.

They run with Practically no Noise or Vibration.

All working parts are very easy of Access.

Built to suit your Particular Requirements.

Two Cylinder Compound, Vertical Forced Lubrication, Quick Revolution Steam Engine, with Combined Throttle and Expansion Governor.

All the materials used in the Manufacture of Vertical, Quick Revolution Engines must be the best obtainable. In the construction of our Engines particular attention has been paid to this feature; the materials supplied being in accordance with **British Admiralty Specifications.** All Engines are tested under steam before leaving our works.

We shall be pleased to furnish Specifications and further information.

The Power Feature in Prominent Canadian Mfg. Plants

Staff Article

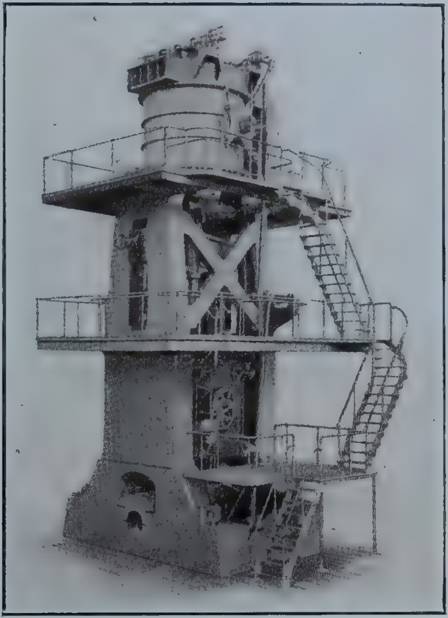
The contents of this illustrated descriptive article are indicative of a variety and purpose of equipment for power generation and transmission, and serve to show that plant location and nature of product contribute largely to the detail and unit combination selected and installed. Again, the increasing recognition of the necessity of heating and ventilating our factories brings into prominence a line of equipment closely allied with that of power generation and transmission.

THE CANADIAN FURNACE CO.

THE Canadian Furnace Co. recently started operations at their new plant, Port Colborne, Ont., for the manufacture of pig iron. The furnace was successfully blown-in on September 27, and on the following day a heat was drawn. The site of the plant is called Victoria. It is situated at the junction of the Welland Canal and Lake Erie, with a frontage of 2,200 ft. to the canal, 660 ft. of which is already docked; the remainder to be converted into dockage as fast as improvements can be carried out. Where the furnace now stands was originally under water to a depth of 5 ft. The bottom, however, is rock, upon which the foundations were laid by means of cofferdams.

Stoves.

For heating the furnace blast, three stoves have been installed by the Variety Iron & Steel Co. They are of the upblast vertical type, made of steel plate and lined with fire brick, 250,000 bricks being required for each stove. The stoves are located near the furnace, are 85 ft. high and 20 ft. diameter inside, and have a connecting platform on the top. They are arranged so as to work in series. While two are being heated by the waste furnace gases, the third, having previously been heated, is warming the air which is passing through from the blowing engines to the tuyeres. The furnace gases pass through the 6 ft. diameter downcomer which connects the furnace top with the stoves and is equipped at the top with two bleeders which are set to go off automatically when the pressure rises above a certain point. In the downcomer is installed a gravity type dust catcher which is set above the tracks, allowing the cars to go under and carry away the dust when necessary.



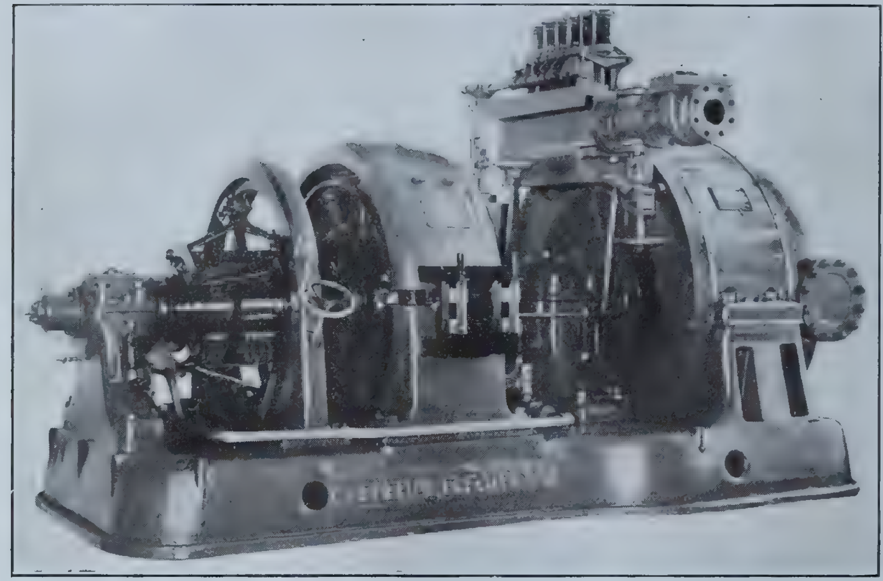
SINGLE UNIT, VERTICAL LONG CROSS-HEAD BLOWING ENGINE.

Boilers.

The boiler house is 120 ft. long by 35 ft. wide and is of steel and brick construction, the steel work being supplied by the Canada Foundry Co. The boilers are of the vertical water tube type, manufactured and installed by the Wickes Boiler Co., Saginaw, Michigan. The 8 units chosen are of 300 horsepower each, two in a battery; making a total of 2,400 horse-power, thus a very flexible and accessible plant. The boiler working pressure is 150 lbs. per sq. inch.

GENERAL VIEW OF PLANT FROM YARD ENTRANCE.

The Dutch oven type of furnace is installed in connection with the boilers, the arrangement being recognized as a most economical and satisfactory method of burning bituminous coal. Besides the hand-fired grates for burning coal, each boiler has two flues through which blast furnace gas may be introduced into the furnace, thus affording a further economy by using combustible gases that are so often allowed to escape. The Dutch oven is especially helpful for the combustion of this gas as it permits of a very thorough mixing of air and gas, and maintains a temperature close to ignition point of gases, until the latter reach the heating furnace.



300 K.W. CURTIS TURBO-GENERATOR.

The travel of the gases through the boiler proper is unusually long and closely confined to the heating surface. The gases leave the boilers through short steel necks to the underground smoke flue leading to the stack. The underground smoke flue has the advantage of not interfering with the cleaning of the soot from the heating surface. Soot cleaning doors are located at convenient points in the setting. These doors are reached by the aid of platforms to facilitate blowing the soot off the heating surface. There are two manholes in the upper and lower drums to allow for close inspection of the interior. All the steam piping was furnished by the Best Mfg. Co., Pittsburgh, the main steam line being 14 in. diameter with 6 in. diameter leads to the boilers. Between the boiler house and stoves is a brick stack, 150 ft. high and 10 ft. diameter inside, built by the Heine Chimney Co., Chicago.

Power House.

The power house is of substantial brick construction and is 80 ft. long by 60 ft. wide, inclusive of the pump pit. It contains the blowing engines, the electric power generating sets, pumps, etc. The blowing engines, supplied by the Allis-Chalmers Co., Milwaukee, Wis., are of the compound long crosshead vertical type, with the air cylinders located above the steam cylinders. The H.P. steam cylinder is 48 in. diameter and the L.P. 84 ins. diameter, while the air cylinders are 84 ins. diameter on both sides. The stroke is 66 ins. Corliss valves are fitted to the steam cylinders. The guaranteed capacity of the blowing engines is 380 cu. ft. of air per revolution when running at 55 r.p.m. against a pressure of 30 lbs. per sq. in. The normal speed, however, is about 40 r.p.m., and pressure 15 pounds. The engines are of the same type and make as others installed at the Buffalo plant where they have given very satisfactory service.

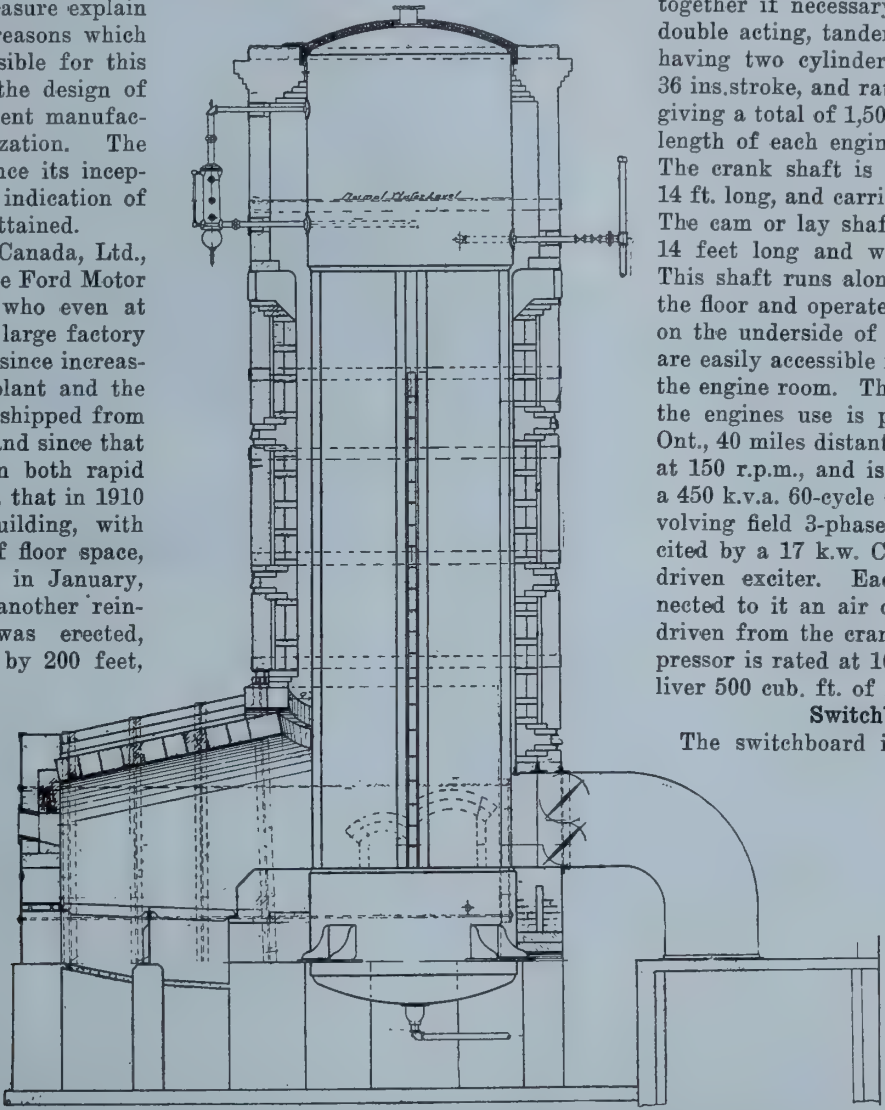
An interesting feature regarding these blowers is that they can be operated independently or as a compound unit by a suitable arrangement of the steam and exhaust piping. The H. P. side can be operated as a simple blower taking steam at boiler pressure. Likewise, the L.P. side can be run independently although in this case a reducing valve would have to be used to reduce the boiler pressure to what would be the receiver pressure when the engines were running compound.

The company generate their own power, and for this purpose have installed two Curtis impulse type steam turbines which are direct-connected to 300 K.W. D.C. generators 125-250 volt, three wire, and run at 1800 r.p.m. These sets were supplied by the Canadian General Electric Co. The six panel switchboard is equipped with the usual instruments and was supplied by the Canadian General Electric Co. A 10-ton overhead hand travelling crane, built by the Euclid Crane Co., Cleveland, Ohio, serves the power house.

On one side of the power house is the pump pit, containing the pumps, condensers, etc. The condenser was supplied by the Deane Steam Pump Co., Holyoke, Mass., who also supplied a duplex type condenser pump, 20-26--24 in. A Cochrane heater provides feed water at 130 degrees Fah. The heater was supplied by the Canadian Allis-Chalmers Co., and in connection with it are two Worthington 12-17-12 in. boiler feed pumps, duplex type. The stand pipe is fed with water from the lake and for

BOILER BATTERY PREVIOUS TO ERECTION OF BOILER HOUSE.

this purpose two Worthington 16-18-18 in. duplex steam pumps have been installed. The stand pipe located between the power house and the furnace is of steel construction, 18 ft. diameter and 65 ft. high, and was supplied and erected by the Canadian Allis-Chalmers Co.



SECTION THROUGH BOILER SETTING AS ARRANGED FOR UTILIZATION OF WASTE HEAT. CANADIAN FURNACE CO. PLANT.

◆

FORD MOTOR CO. OF CANADA, LTD.

THE history of the Ford Car has been one of phenomenal success, and a visit to the Canadian home of the "Ford" will in a great measure explain the reason for this. The reasons which are perhaps chiefly responsible for this success are standardizing the design of the car together with efficient manufacturing methods and organization. The growth of the company since its inception, nine years ago, is an indication of the success that has been attained.

The Ford Motor Co. of Canada, Ltd., was organized in 1904 by the Ford Motor Co. of Detroit, Michigan, who even at that time were operating a large factory in the latter city, and have since increased enormously both the plant and the output. The first car was shipped from Walkerville, Ont., in 1905, and since that date the progress has been both rapid and continuous, so much so, that in 1910 a three-storey concrete building, with about 19,000 square feet of floor space, was built and completed in January, 1911. In the same year, another reinforced concrete building was erected, having four floors 75 feet by 200 feet, containing 60,000 square feet of floor area, and built over the river bank. A new office building was also built this year.

In 1912 the capital stock of the Company was increased from $150,000 to $1,000,000 and the name changed to the Ford Motor Co., of Canada, Ltd. About this time, the district in the vicinity of the factory was incorporated as a town and given the name of Ford. This district adjoins the town of Walkerville, but the town of Ford has a separate municipal organization. In 1902 another concrete factory was built 75 feet wide by 505 ft. long and was a continuation of the 1911 building. This extension completed the main building which is now 705 feet long by 75 feet wide, and is built parallel to the river. The Company have a site covering 60 acres situated on the Detroit River and have a siding connection with the Grand Trunk and Essex Terminal Railway. On that part of the property across the main road and directly opposite the factory, a modern power house and boiler room have been built. The location of the plant is good as cheap power in the form of natural gas is used and shipping facilities to the various markets are of the best.

Power Plant.

Crossing the road we come to the power house which is a brick building of handsome appearance and about 60 ft. square. The roof trusses are steel with a concrete roof. The windows with steel sash extend almost the full height of the building and on three sides. The walls inside are lined with white glazed brick, with the result that this is perhaps the brightest and cleanest power house t obe seen anywhere. The equipment generally is of the most modern type.

The power installation consists of two horizontal gas engines made by the Hooven, Owens & Rentschler Co., Hamilton, Ohio, to the designs of Edward Grey, an engineer on the staff of the Ford Co. at Detroit. Both engines are identical in design except that they are right and left-hand. They are operated as separate units, but can be operated together if necessary. They are of the double acting, tandem 4-cycle type, each having two cylinders 24 ins., diam. by 36 ins.stroke, and rated at 750 h.p. each; giving a total of 1,500 h.p. available. The length of each engine overall is 40 feet. The crank shaft is 18 ins. diameter by 14 ft. long, and carries a 20 ton flywheel. The cam or lay shaft is 4¾ ins., diam., 14 feet long and weighs 1,900 pounds. This shaft runs alongside the engine on the floor and operates the valves located on the underside of the cylinders which are easily accessible from the floor under the engine room. The natural gas which the engines use is piped from Tilbury, Ont., 40 miles distant. Each engine runs at 150 r.p.m., and is direct-connected to a 450 k.v.a. 60-cycle Crocker-Wheeler revolving field 3-phase generator, and excited by a 17 k.w. Crocker-Wheeler belt driven exciter. Each engine has cennected to it an air compressor which is driven from the crank shaft. Each compressor is rated at 100 h.p., and will deliver 500 cub. ft. of free air per minute.

Switchboard.

The switchboard is of the automatic type and was supplied by the Canadian General Electric Co. It has panels made of natural black slate and is mounted on iron pipe framework with a full complement of instruments which have a dull black finish. The switchboard controls are as follows: — 2-480 volt, 500 k.w. 3-phase, 60-cycle engine driven generators; 2-110 volt, 17 k.w. exciters; 1-35 k.w. 110 volts, exciter direct connected to a 50 h.p. motor; 3-180 feeders; 1-100 k.w. 3-phase transformer; 3-35 k.w. single phase, 3 wire lighting feeders.

The apparatus controlling the above is mounted on a bench board to be seen in the illustration. The bench board is fitted with a number of switches and illuminated indicators. A 20-ton hand-operated overhead Niles travelling crane is installed and mercury vapor lamps are used for lighting.

It will be interesting to note that there is operating at the Detroit factory a 5,000 H.P. gas engine made by the same firm as the one described above. This unit is perhaps one of the largest gas engines installed in a factory on this continent.

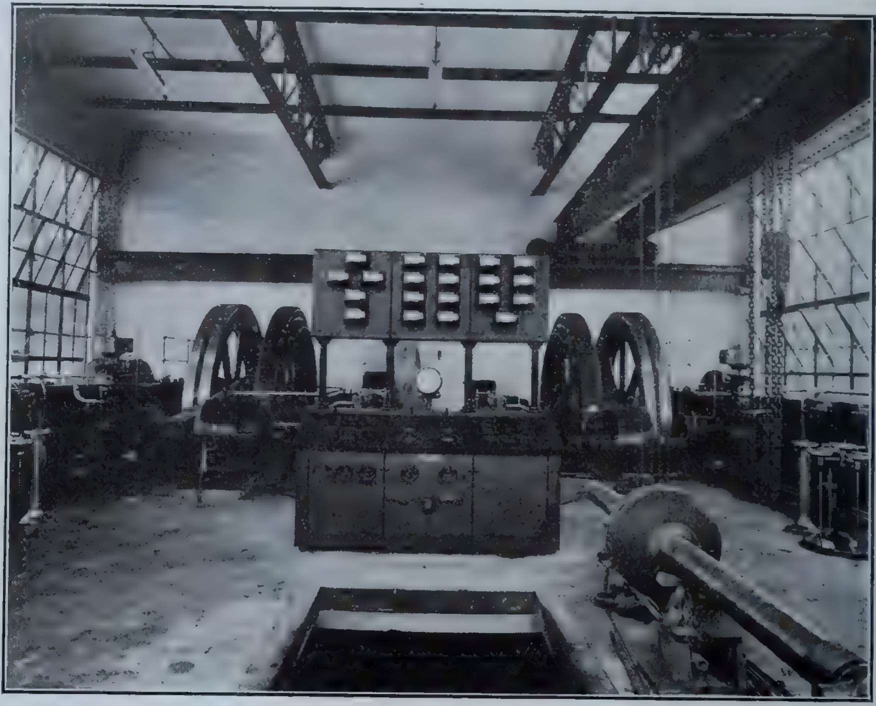
Boiler Room.

The boiler room is located near the power house and is connected to it by an underground passage terminating in the basement. The building is of substantial brick construction, 90x80 ft., and has steel roof trusses with concrete roof. The windows are fitted with "Kahn" steel sash and ribbed glass; a number being made to open, permitting of ample ventilation.

There are installed four Goldie & McCulloch horizontal return tubular boilers of 90 h.p. each, 60 in. diameter by 16 ft. long. The boilers are capable of carrying 140 lbs. steam pressure, but at present are running at 90 pounds. Each boiler is equipped with a set of burners for using natural gas at 11 ozs. pressure. Near the boilers is a Goldie & McCulloch No. 4 "Ideal" feed water heater rated at 125 h.p. and, in connection with it, a duplex boiler feed pump, 5½x3½x6 ins. for boiler feeding. A "Burnham" vacuum pump 16x18 ins. takes the drains from the heating system and returns them to the heater.

In the basement, under one end of the boiler room, are two 6-in. steam turbine double suction centrifugal pumps for pumping hot water from the boilers to the heating coils on the roof of the main factory building. Each pump has a capacity of 1,000 gallons per minute against a head of 50 ft. at 2,500 r.p.m., and is direct connected to a No. 5 Buffalo Forge Co. "Spiro" steam turbine, developing 22 h.p. at 90 lbs. steam pressure, non-condensing. Adjoining these sets is a 1,000 gallon Worthington duplex steam pump for supplying water to the two tanks over the main factory building.

In the boiler room is installed a steam-driven air compressor supplied by the Bury Compressor Co., Erie, Pa. This machine has cylinders 12x12x12 ins. stroke with a capacity of 310 cu. ft. of free air per minute against a pressure of 100 pounds at 200 r.p.m. Under these conditions it is rated at 62 h.p. It is fitted with cushioned poppet inlet and discharge valves, and has forced feed lubrication. All the high pressure steam pipes are fitted with crane extra heavy fittings, and Philip Carey Co. pipe covering is used throughout the plant.



INTERIOR OF POWER HOUSE.

GENERAL VIEW OF PLANT—THE FORD MOTOR CO. OF CANADA, LTD.

INTERNATIONAL MALLEABLE IRON CO.

THE International Malleable Iron Co., Ltd., have built a large foundry at Guelph, Ont., for the manufacture of malleable and grey iron castings, at the eastern end of the city, on a site covering about 12 acres and adjoining the Canadian Pacific Railway tracks. The company is operating under the auspices of the Illinois Malleable Iron Co., of Chicago, Ill., who, in conjunction with W. A. Mahoney, architect, Guelph, were responsible for the lay-out and construction of the plant; they will, therefore, have the benefit of the experience gained in this class of work by the parent company who are one of the largest manufacturers of malleable castings in the United States. The site is level, and being near the railway, every facility is offered for the receiving of the raw materials and the shipment of the product; a siding on the property leads into the stockyard where will be laid an industrial track system, when materials will be conveyed directly into the foundry. The siding also passes along, outside the annealing room where coal is delivered direct from the cars to the annealing oven furnaces, through openings in the wall.

Boiler.

A waste heat boiler has been installed in connection with the air furnace in order to utilize the large amount of heat in the gases leaving the furnace. The boiler is a 400 horse-power vertical water tube unit, built and installed by the Wickes Boiler Co., Saginaw, Mich. The design is especially adapted to its particular purposes, as the floor space required for the boiler and auxiliary furnace is a minimum. Another advantage that tends toward the greatest absorption of heat is the long travel of the gases in close confinement to the heating surface.

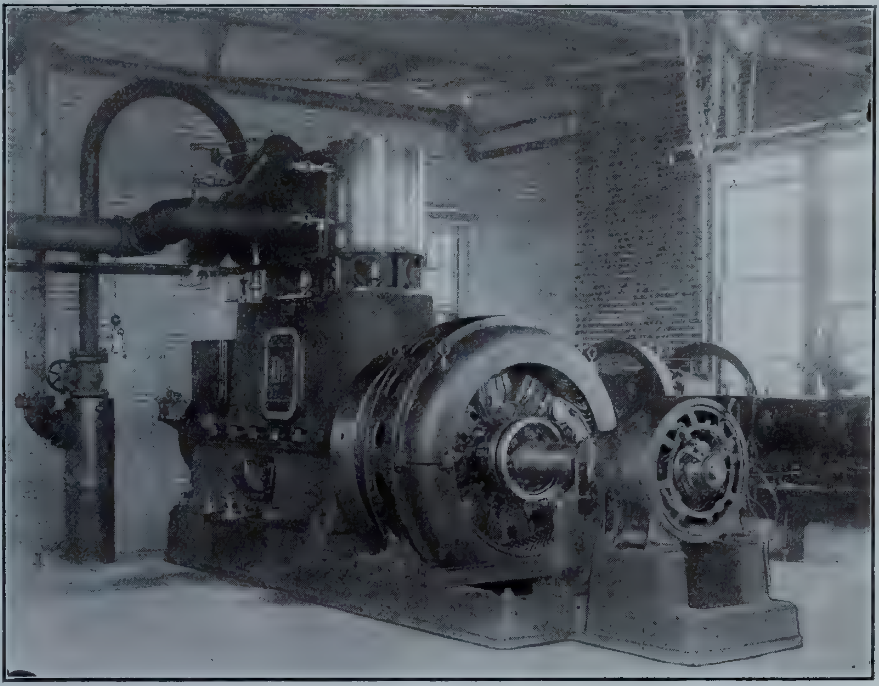
Fire brick dampers are installed at suitable locations to permit the use of the boiler as a direct fired unit in case the steam is desired when the air furnace is down. The auxiliary furnace is hand fired, and will be used to obtain the desired output from the boiler during the charging periods in addition. A waste heat by-pass flue around the boiler to the stack has been provided so that should anything happen to the boiler or boiler setting, it would be possible to take off the heat without damage to the furnace. The total floor space required for the flues, boiler, auxiliary furnace and stack is approximately 25 ft. square. The stack, of perforated radial blocks, is 110 ft. high above top of foundation, and was built by the Alphons Custodis Co., New York. It is 3 ft. 6 ins. diameter at the top, and the foundation of concrete is 15 ft. square by 5 ft. deep. All round column construction is the particular type, and a sectional fire brick lining, 4 in. thick, supported every 20 ft. on the inside by fire brick corbels built out from the main walls, extends throughout the whole height.

The stack is built for high temperatures, the inner core being not only of firebrick, but in addition having the main walls reinforced by internal steel bands built at intervals into the masonry. Between the lining and the main walls there is a 2 in. air space, and each section of lining is built free at the top to allow for expansion under high temperatures. The particular feature of construction is that all the blocks are cut on radial lines to fit the diameter. They are also perforated vertically, the mortar in the horizontal joints entering the holes, keying the blocks, as it were, together. The material is manufactured exclusively for chimney blocks, and has a crushing strength averaging over 6,000 lbs. per square inch.

Power Plant.

The power house contains a "Leonard" high speed engine, rated at 300 i.h.p., running 375 r.p.m., with steam pressure of 125 pounds. It is of the vertical compound type, with cylinders 15 and 20 in. diameter by 10 in. stroke. The engine is totally enclosed, and is equipped with oil relay expansion gear operating the high pressure valve and regulating the cut off in accordance with the engine load. The engine is direct connected to a 150 k.v.a. Canadian Westinghouse generator supplying current at 600 volts, 3-phase, 25 cycles. The 6 k.w. exciter is on the main shaft. The switchboard was supplied by the Canadian Westinghouse Co., and has two slate panels equipped with 3 ammeters, a voltmeter, and the necessary switches.

The air compressor was supplied by the Bury Compressor Co., Erie, Pa., and is of the horizontal simple steam driven type, with cylinders 12 and 12 diameter by 14 in. stroke. Its capacity is 330 cubic feet of free air per minute at 180 r.p.m., against a pressure of 100 pounds, and under these conditions approximately 66 h.p. can be developed. The steam and air cylinders are in a straight line, and have a common piston rod. The compressor has an enclosed crank case, and is fitted with the "Bury" automatic, pneumatic forced lubrication system, designed to increase the efficiency of the machine, and to reduce loss of oil to a minimum. The air inlet and discharge valves are of the cushioned poppet type, rendering the compressor noiseless in operation. The air receiver is 48 in. diameter by 12 feet long, and is situated in the foundry.



"LEONARD" ENGINE AND GENERATOR WITH "BURY" COMPRESSOR.

An "Ideal" feed water heater and purifier is installed, and was supplied by the Goldie & McCulloch Co., Galt. It is an open type heater, 5 ft. diameter by 14 ft. high, and is fed with city water by gravity and heated by exhaust steam from the engine. Feed water is pumped to the boilers by two 7½-4½-10 in. duplex pumps, which were supplied by the Canadian Allis-Chalmers Co. The steam pipes and fittings are extra heavy quality, and were supplied by the Crane Co., Chicago. They are covered with Johns-Manville Co. asbestos pipe covering. A hand travelling crane is installed and equipped with a 2 ton chain block.

Heating System.

The heating system was installed by the New York Blower Co., Chicago, and consists of a 200 in. steel plate motor driven fan, standard for 60,000 cu. ft. of air per minute, together with a heating coil of sufficient capacity to heat the above quantity of air to around 120 deg. through 12,000 lineal feet of 1 in. pipe arranged in two groups. The heating coil is raised to a sufficient height so that the water drains back to the feed water heater. The apparatus is designed for using exhaust steam from the main engine and steam supplied direct from the boiler through a pressure reducing valve. The apparatus operates on low pressure steam at all times.

The buildings heated consist of the main foundry, cleaning room, machine shop, pattern shop, and core rooms. The warm air is distributed through galvanized iron ducts running the whole length of the foundry, with branches leading off at various points for distribution. The fan is located in a separate room near the power house.

CAN. FAIRBANKS-MORSE TORONTO PLANT.

AT the plant of the Canadian Fairbanks-Morse Co., Toronto, hydro-electric power is used, being stepped down at the transformers from 13,200 to 550 volts. The switchboard was installed by the Canadian Westinghouse Co. It has eleven grey marble panels, two only of which are being used at present. The usual equipment of ammeters, voltmeters and circuit breakers furnishes the different panels.

There is a Canadian Fairbanks 40 k.w. 25-cycle, 3 phase, 750 r.p.m. motor generator set for supplying d.c. current at 220 volts to the crane motors. Power is distributed to the motors in the various shops at 550 volts and 110 volts to the lighting circuit. Canadian Fairbanks Co. motors are installed throughout, and Mazda and Sunbeam 200 watt and 400 watt lamps are used for lighting.

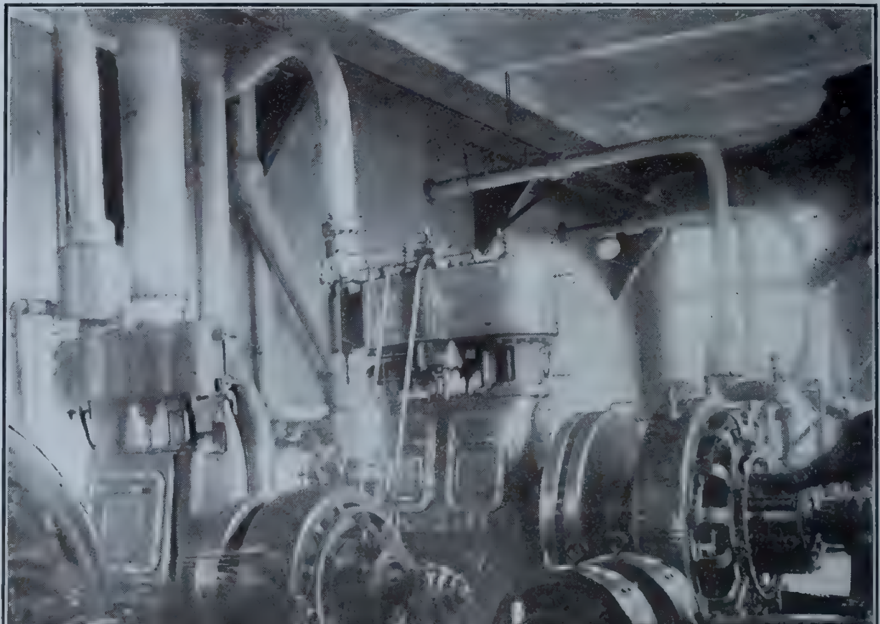
A Canadian Rand air compressor supplies air to the plant. This machine is steam driven, having cross compound steam and air cylinders, the steam cylinders being 11 and 18 in. diameter, and the air cylinders 16 and 9 in. diameter, by 16 in. stroke in both cases. The compressor has a capacity of 744 cub. ft. of free air per minute against a pressure of 100 pounds at a speed of 200 r.p.m. A Canadian Fairbanks 6-8-12 vacuum pump takes the drains from the heating coils and returns them to a Cochrane feed water heater. Two Canadian Fairbanks 6-4-6 boiler feed pumps are also installed.

In the boiler room is a battery of four boilers which consists of one 150 h.p. Babcock & Wilcox water tube boiler having a working pressure of 150 pounds; two "Brownell" return tubular boilers and one return tubular boiler by the John Inglis & Co. The three latter boilers are of 75 h.p. each, and have a working pressure of 70 pounds. The steel stack is 100 ft. high by 40 in. diameter. At the back of the boiler room is the coal storage.

CANADIAN LOCOMOTIVE CO., KINGSTON, ONT.

THE works of the Canadian Locomotive Co., Ltd., at Kingston, Ont., are the oldest in Canada devoted to locomotive construction, dating back more than sixty years. They were established in 1850 and were taken over by the present company, organized by Mr. Aemilius Jarvis, of Toronto, in 1911.

A large amount of money has been spent in the modernization of the plant, and where the production two years ago was barely six engines per month it is at the present time twelve; and when the improvements and betterments which are now being proceeded with are completed, the output will be increased to twenty-five locomotives per month.



INTERIOR OF POWER HOUSE, SHOWING ENGINES AND GENERATORS. CANADIAN LOCOMOTIVE CO.

The problem of how best to remodel the works was one beset with difficulties, not the least of which was the restricted nature of the site of the existing plant. This site, however, it was decided to retain, as it is possessed of several important advantages. It has excellent track connections with the Grand Trunk Railway and lies on the shore of Lake Ontario, with unloading slips on two sides of the plant, enabling raw material to be brought in by water.

The first step in rebuilding was to get out plans for the new shops to be erected over and around the old ones, that being the only way in which production could be continued during the alterations. This work was entrusted to the firm of Henry Goldmark, consulting engineers, New York. The preparation of detail plans and specifications and the carrying out of the work is in charge of Mr. C. J. Goldmark, a member of the firm. Good progress has been made, the new carpenter and pattern shop, pattern storage, foundry, tank and tender shops being now completed. The pits in the new erecting shop are also built and the foundation work finished; and erection of the steel work is now going forward.

The Power House.

Current for operating these shops is generated in the Company's own power house, erected about eight years ago. It is situated east of the new foundry and is a steel framed building covering an area of 87 ft. by 75 ft., with an annex for the pumps and other auxiliaries. The walls are of reinforced concrete and the flat roof is of hollow tile. A longitudinal fire wall divides the boiler room from the engine room, the former having a width inside of 37 feet 8 inches and the latter 32 feet. Steam at 150 lbs., pressure is raised in six Wicks vertical water tube boilers fitted with Foster superheaters. Four of the boilers are rated at 250 h.p. each, and two at 330 h.p. All are fired by Murphy automatic furnaces in Dutch oven settings. There is a short steel stack 6 feet in diameter through which a draft is induced by a Canadian Buffalo Forge Co. engine driven fan. This installation is in duplicate to avoid breakdowns.

The Dutch oven setting of the furnaces makes the coal handling problem a very simple one. To the south of the power house is an elevated coal bunker, which is filled by a locomotive crane from the yard coal piles or direct from a steamer at the adjacent wharf. An elevated industrial track runs from below this bunker into the boiler house and across the top of the Dutch ovens. Small tip wagons are thus quickly filled up at a chute in the bottom of the coal bunker, run into the boiler house and dumped direct into the furnace hoppers. On their way they pass over a small track scale and are weighed. At present ashes are raked out of the pits by hand and taken away in wheel-barrows; but it is the company's intention to shortly instal an ash disposal system on the suction principle.

The engine room has a dado eight feet high of white tiles, which gives it a very pleasing appearance. It is equipped with a hand operated 5-ton traveller and is lighted by arc and tungsten lamps. There are three generator units with a total nominal capacity of 750 kilowatts. The engines are all by Belliss & Morcom, and the generators by the Canadian Westinghouse Co. These generate direct current at 250 volts.

Compressed air for the whole plant is supplied by two compressor units. One of these is a Belliss & Morcom vertical cross-compound two-stage compressor with a capacity of 2,000 cubic feet of free air per minute at 100 lbs. pressure when running at 250 r.p.m. The second unit is a Canadian Ingersoll-Rand horizontal cross compound Corliss two-stage compressor 1,250 cubic feet capacity per minute at 100 lbs. pressure, running 96 r.p.m. The exhaust from all five units can be discharged to the atmosphere, to the shop heating system, or to a Worthington barometric condenser. A vacuum of about 27 inches is maintained in the latter by a 6-12-10 Knowles vacuum pump, while the condensing water is raised by a No. 8 single stage turbine pump built by the John McDougall Caledonian Iron Works Co., Ltd., Montreal. This is direct driven by a Robb-Armstrong single cylinder vertical engine.

The boiler feed is delivered by two Blake and Buffalo steam pumps, 10-5-10. The water is drawn from Lake Ontario and after passing through a Webster open heater is measured by an automatic recording Venturi meter and is thus checked against the coal, which as previously stated is all weighed. The boiler feed lines are in duplicate, and, as a precaution against the failure of both feed pumps, two No. 9 Korting injectors are always available.

For general water service there is a 10-7-2 steam pump by the Canada Foundry Co.; and the same firm built the two fire pumps, the larger of which is a 20-12-6 and the other a 16-9-12. For handling the returns from the heating system there are two Burnham 10-16-16 vacuum pumps, which deliver to the heater or to sewer as may be desired.

The engine room contains a handsome marble switchboard of ten panels, and each shop has its own feeder line controlled from a separate panel in the switch-board, the whole of the motors throughout the plant operating at 240 volts. To maintain an even voltage in the lighting circuits there is a motor generator balancing set of 10 kilowatt generator capacity.

From the power house a pipe tunnel runs across the site as far as the old machine shop. This accommodates the high and low pressure steam pipes, water service pipes, etc.

❖

PROTECTING BELTS, SHAFTS AND PULLEYS.

THE accompanying instructions have been issued by a Chicago concern relative to the prevention of accidents due to contact with moving belts, shafts and pulleys:—

Belt, rope and cable transmission shall be arranged, so far as possible, to be easily guarded.

Pipe or angle railing placed 18 inches from the pulley or belt shall be provided where there is little danger of anyone getting caught by the belt.

Wire-mesh or perforated-plate casing shall be provided where the location of a belt is such that persons are liable to get caught between the belt and the pulley.

Where the belt is located in such a position that, should it break, flying ends will strike persons passing by the belt, it should be inclosed by a suitable guard.

The full width of a belt should be allowed between two pulleys or a pulley and a hanger on shafting so as to prevent the belt from becoming wedged and possibly pulling down the line shafting.

Belt splicing shall be made so as to eliminate ragged edges or projections which might catch employees' clothing. Endless belts are recommended, especially for high-speed machines.

Belts should be inspected frequently and kept in a condition to avoid accidents. Tight belts should be avoided.

Wherever it is necessary to shift belts, a mechanical device should be provided.

Where it is necessary to unship a belt, a hook or belt-perch should be provided to prevent the belt from resting on the shaft.

Shafting not over 12 inches above floor should be covered.

Shafting over 12 inches and not over 7 feet above floor should be encased or railed off.

Exposed ends of shafting shall be encased or otherwise guarded.

Overhead shafting which must be oiled should be equipped with a walk for the oiler, if practicable.

Electrically driven shafting should be provided with a safety switch, to be used when men are working on it. This switch should be placed at the top of the ladder or in some place where no one will tamper with it.

Shaft couplings should be guarded where safety couplings are not used.

To prevent gears or pulleys from working off the ends of shafting, shaft ends shall project at least the diameter of the shaft beyond the hub of the gear or pulley, so that the key can be locked in place.

Hangers for shafting shall be particularly strong and well secured.

All projecting keys in shafting, when exposed so that a person might get caught thereon, shall be guarded or cut off.

Wherever possible, cotter pins or spring washers should be provided to prevent nuts from working off the ends of bolts.

Setscrews must be guarded, countersunk or placed in safety collar with flanges high enough so that the setscrew head will not project above the flange.

Because of the dangers incident to hoisting material by means of line shafting, it is forbidden that any hoisting be done in this manner. All hoisting shall be done either with hand tackle and block, or with regular hoisting machinery.

❖

Estevan Lignite.—R. M. Blackburn, chief inspector of boilers for Saskatchewan, will leave shortly to conduct experiments with Estevan lignite coal at the plant of the Dominion Coal Co., Sydney, N.S. He will be accompanied by S. N. Darling, who is in charge of the Government experimental plant at Estevan, and the tests will probably cover the better part of two weeks. Three weeks ago, two carloads of carbonized screenings from the Estevan mines were shipped to the East, and this fuel is to be used in determining the efficiency of the fuel in a special type of furnace, only two of which are in operation in this country, and both at Cape Breton.

Changing From Oil Fuel to Coal For Steam Boiler Firing

By F. V. Hetzel*

General observations intended to throw some light on the methods to be adopted when installing coal and ash-handling machinery equipment in boiler plants which have been previously burning oil. Individual peculiarity of location and arrangement will call for particular treatment and the service of engineers trained to the special work.

WITH the rise in the price of fuel oil, many power houses are facing the problem of burning coal instead of oil. Heretofore, these power houses favorably situated near oil fields have obtained their oil at low cost, but oil prices have been going up so steadily that many managers have come to the conclusion that it will pay them to make the alterations in their boiler houses which a change in fuel makes necessary. Boiler settings must be altered, flues and stacks made larger, and provision made for storing and handling coal and ashes. After the simplicity of piping oil to the boiler furnaces, taking care of coal and getting rid of ashes is a disagreeable necessity, but with the wide-spread use of conveying machinery, coal and ash-handling equipments for boiler houses have been brought to a state of refinement, and managers who are facing this problem will find that such apparatus can be adapted to any conditions of site, size of boiler house, or amount of storage.

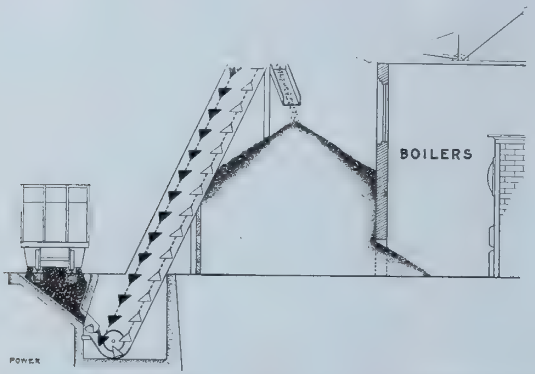


FIG. 1—WHEN THERE IS NO ROOM FOR OVERHEAD STORAGE.

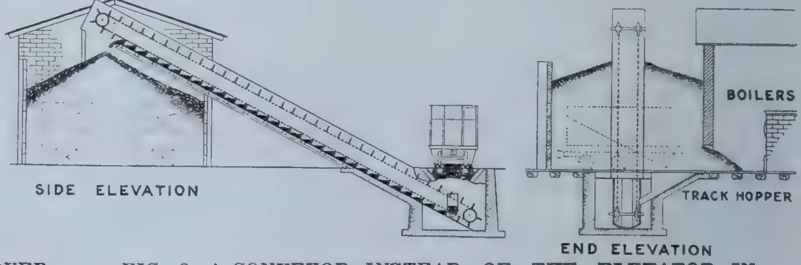

FIG. 2—A CONVEYOR INSTEAD OF THE ELEVATOR IN FIG. 1.

Assuming that there is a railroad siding at the plant, it will be found advisable in most cases to put in a track hopper with a conveyor or an elevator, rather than build a trestle, and dump cars on it. If a trestle dump is used, the coal is spread over a considerable length, and the fireman has to do more wheeling and shoveling to get his coal. Moreover, the first cost of a trestle, and the expensive maintenance of a wood trestle, generally offset what may appear at first as desirable simplicity.

For a hand-fired boiler plant, it is often convenient to store coal just outside the wall of the house, and let the coal flow through holes in the wall to within reach of the fireman. This may suit existing plants when there is no room for overhead storage. In such cases a bulkhead is built parallel to the wall of the house, and the intervening space filled by a chute from the head of an elevator, Fig. 1, or from a conveyor, Fig. 2, or by means of a combination of elevator and conveyor, Fig. 3. The machinery for such a plant is simple and cheap, and the cost of unloading from cars and delivering to bins need not exceed 2 cents a ton.

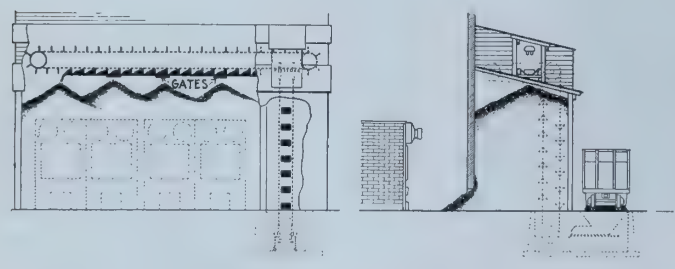

FIG. 3—A COMBINATION ELEVATOR AND CONVEYOR.

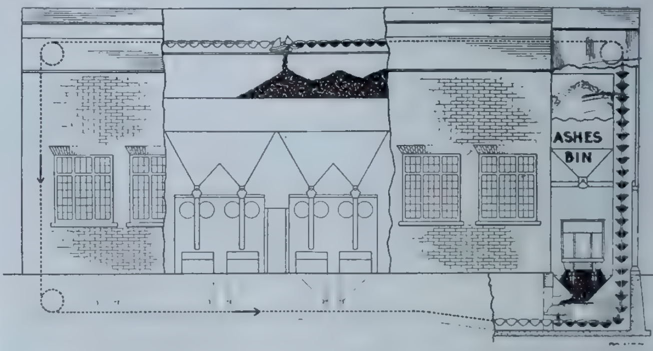

FIG. 4—TYPICAL INSTALLATION OF PIVOTED BUCKET CARRIER.

For every 100 tons of coal burned, there does not usually result more than 10 tons of ashes, and for a small house, it does not pay to install a separate conveyor to gather ashes from in front of the boilers. A wheelbarrow or a hand cart is usually best. An ash elevator and a storage bin are often used, Fig. 5, in such plants. The ashes are stored at a height to flow by gravity into cars or carts, and as they are handled but once, there is no need for the extra labor of loading, as is the case where ashes are piled on a dump until the time comes to take them away.

Since one man cannot fire more than 500 h.p. of boilers under normal conditions, it becomes necessary in larger plants to employ more firemen, or to install stokers and a gravity supply of coal from overhead storage. It may not be possible in all altered boiler plants to install overhead bins and spouts, but where it is possible, managers should consider not only the first cost of bins and conveyors, but also the fact that the wages of common labor are increasing each year, that in many places it is difficult to hire men for the hot and laborious job of firing boilers by hand, and that it generally pays to invest $5,000 in bins and conveyors for every fireman or coal passer whose services can be rendered unnecessary.

---

*Chief Engineer, the Link Belt Co., Philadelphia and Chicago.

If overhead storage is decided on, the bins can be separate for each boiler, or one long bin can be used. The latter is the cheapest way to get a large amount of storage, particularly if the bin is of the suspension or bag-bottom form. The bin should be high enough to permit boiler tubes to be cleaned or removed, and there should be room enough over the bin to put in the coal conveyor. The bin can be filled by a separate coal conveyor, but since in most large plants the problem of quickly disposing of ashes is an important one, a convenient way is to combine the coal conveyor and the ash conveyor in one, and use a machine of the pivoted-bucket type. Figs. 4 and 6 show typical installations of pivoted-bucket carriers. These include a track-hopper dump, a feeder of some kind, a crusher and the carrier taking coal from the crusher and delivering it to the overhead bins, or taking ashes from the hoppers under the boilers and delivering them to the ash storage overhead. If there is no basement for the lower run of the carrier, or if hoppers cannot be built under the boilers, all that is necessary is a trench in the boiler-room floor to receive the carrier. Ashes are then raked from the boiler ashpits into the lower run of the carrier.

Pivoted-bucket carriers are of several forms. A type quite commonly used has overlapping lips, see Fig. 7, to prevent the spill of material between the buckets. Cams or strikers on the ends of the buckets engage a dumper which travels along the top run, and the contents of each bucket are poured out at any point desired.

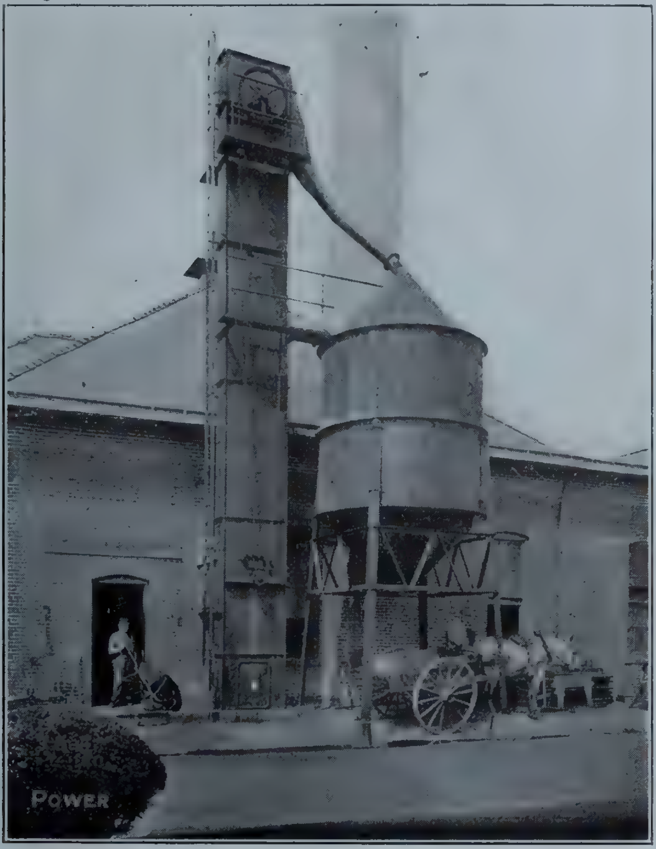

FIG. 5—ASH ELEVATOR AND STORAGE BIN.

The Morrison Water Tube Boiler is illustrated clearly in a bulletin recently issued by the Morrison Boiler Co. Sharon, Pa. One page contains a schedule of information which the company require before submitting quotations.

ROLLER AND BALL BEARINGS.

At the Institution of Automobile Engineers recently, Professor John Goodman, of the Leeds University, gave a lecture on the subject of roller and ball bearings. Professor Goodman has been making a consistent study of this question for fifteen years, in the course of which innumerable experiments have been made on various types of both ball and roller bearings under many different conditions of load and at various speeds.

Before dealing with the various criticisms he made, it may be well, says The Engineer, to give one of the most valuable results to which his investigations have led, namely, the establishment of a formula which will give the maximum working load in pounds to be allowed for any given ball bearing. The formula reads:—

$$\frac{K\,m\,d^3}{N\,D + C\,d}$$

where

m = the number of balls in the bearing,
d = diameter of the balls in inches,
N = revolutions per minute,
D = diameter of ball race, diameter being taken from the point of contact of the ball with the race, or for a thrust bearing D = the diameter taken from the centres of the balls.

The constants C and K are as follows:

For Thrust Bearings.

	C.	K.
Flat races	200	500,000
Hollow races	200	from 1,000,000 when the radius of the race is about twice that of the ball to 1,250,000 when the radius of the race is 9-16th that of the ball.

For Journal Bearings.

	C.	K.
Flat races	2000	1,000,000
Hollow races	2000	from 2,000,000 where the radius of the race is about twice that of the ball to 2,500,000 where the radius of the race is about 9-16th that of the ball.

Roller Bearings.

The lecturer dealt first with the question of roller bearings, and commenced by showing Osborne Reynold's diagram illustrating the manner in which the resistance due to friction occurs. The first point he impressed upon his audience was that when an elastic roller rolls on an elastic bed there is always slipping, and his tests show that the amount of slipping depends very largely upon the load, i.e., there is a small amount of slip with a very light load and a comparatively large amount of slip with a heavy load.

In the case of roller bearings, end thrust results in the rollers wearing right through the end of the cage, and, in addition, sets up a vibratory action, which enormously increases the friction of the bearing. A case was mentioned in which this vibration was so large in a particular factory that the bottles on the shelves of the chemical department overhead began to fall over, and the bearings had to be removed. End thrust, it was pointed out, may easily amount to a quarter or a third of the total load on the bearing. With a 10-ton load on a bearing, from 2¼ to 3 tons end pressure would be encountered, and the direction of the end thrust would always reverse when the direction of the rotation of the shaft was reversed. The case was also mentioned of forty or fifty railway wagons fitted with roller bearings which had to be put out of service owing to the amount of end thrust which in some instances had caused the casing to be worn right through.

This end thrust with roller bearings occurs however good the workmanship, although one form of roller bearing was illustrated in which the length of the roller was approximately equivalent to the diameter, and, whether due to this fact or not was not stated, the end thrust was almost absent. Comment was made upon the satisfactory service given by the plain roller bearings used in light railway wagons of the Koppel type, the bearings being practically pieces cut from mild steel rods with the ends rounded. The results obtained with this very cheap form have, curiously enough, been found to be almost equal to those of the most expensive type of roller bearing.

Professor Goodman also investigated the question of whether the efficiency of roller bearings was in any degree affected by the degree of accuracy in the workmanship, but he has come to the conclusion that it is not so, because, after going to the fullest possible trouble to obtain bearings of the highest class, the results obtained were no better than with the cheaper forms. Better results were achieved with long rollers, but these, he said, could not be regarded by any means as an unqualified success.

Summing up end thrust troubles, Professor Goodman said that the friction on the bearings was enormously increased, owing to end thrust. He could give many instances of the seriousness of the wear, and in addition there was the question of rumbling or vibration. With a properly designed roller bearing in which the end thrust was extremely small, the friction was, to all intents and purposes, independent of the lubrication, but when a large amount of end thrust manifested itself, then lubrication made a very considerable difference, for the simple reason that when there was little end thrust a pure rolling action was obtained, whereas with end thrust there was a large amount of friction between the ends of the cage and the flange of the casing. In these instances lubrication did good.

Friction with roller bearings has been determined to be almost independent of the speed, and in all roller bearings, bad and good, the starting effort is very little greater than the running effort, which was admitted to be a point in their favour for machinery constantly starting and stopping. With the worst type of roller bearing the friction was lower than in an ordinary bearing with poor lubrication, but a roller bearing in these conditions was not so good as a bearing running in a bath of oil.

Ball Bearings.

Passing on to the virtues of the ball bearing, the lecturer pointed out that with it there is no end thrust at all, and the friction is very much less than in the majority of roller bearings; hence, there was a good deal to be said in its favor. It might be said against this statement that a ball bearing only bears on a point, whereas the roller bearing bears on a line; hence, a ball bearing of a certain size could not possibly carry so high a load as a roller bearing.

He admitted that there was an element of truth in this, but it was not the whole truth. With equally good material in rollers and balls, and in the absence of end thrust on the roller bearing, the argument would hold rigidly, but since end thrust did come in with the roller bearing, with other troubles in consequence, practically any type of ball bearing was able to carry a much bigger load than any roller bearing.

Features of Interest Relative to Boiler Firing*

By W. M. Faber **

The author in his paper takes the stand that hand-firing if properly directed and performed, is not without its many good points, but as the matter of performance usually falls far short of the ideal, mechanical stoking along chain grate lines is recommended on account of its tried efficiency.

THE man with the shovel is told by the expert to fire in a manner called the "coking method," and, if reasonably intelligent, he soon finds that he is putting the coal through a cycle of operations by which the volatiles are first distilled and driven off, largely by radiant heat from the side walls and arch if it be an extension furnace, and from the incandescent fuel farther within the furnace; burning the resultant coke by a proper admixture of air through the grate bars and finally riddling the ashes into the ash pit at the middle and back section of the furnace, when the grates are as they should be for this method of firing, of the sectional agitating or shaking type.

By so firing, it is possible to get a high furnace efficiency, but it only applies to furnaces equipped with non-automatic grates where hand firing is practised. Even in plants thus equipped, we have trouble because the fireman seldom follows the instructions given him and soon gets back to his old method, which, in most cases, is what is called the spreading system of firing. This is good if properly followed out, but as usually done, it is a source of great waste of fuel, because the fireman persists in firing five or six shovels of coal where three would have done very much better, presumably so that he might sit down between firings for 15 or 20 min.

The Chain Grate Stoker.

Fundamentally, it seems to me, the idea of the chain grate stoker is correct. It carries the coal through the same cycle that the intelligent fireman does when he uses the coking method on a flat grate, and if we could only control the air supply more perfectly and hold the fuel on the grate long enough to insure a thorough burning out, its efficiency would be greatly improved. When chain grate stokers are used, we have come to appreciate that there are certain requirements as regards the physical condition of the coal, aside from its thermal qualifications, that we must consider and provide means for obtaining; an important one being, proper and approximately uniform size of the coal that comes to us either as slack from the mines, or from our crushing plants when run-of-mine is used.

---

*From a paper read before the Cleveland Engineering Society.

**Engineer, the American Steel & Wire Co., Cleveland, Ohio.

Formerly when run-of-mine coal had to be crushed, we considered it in good condition when 85 to 90 per cent. would pass through a 1¼ x 1¼-in. mesh screen, but at the present time we are dissatisfied with this condition of the coal for our stokers, and are endeavoring to get our crushers to crush the coal so that 85 to 90 per cent. will pass through a ¾ x ¾-in. screen. These changes in the mere matter of the sizes of the lumps of coal that make it fit for chain grate stokers have been brought about by the attention that seems to be paid everywhere to the combustible in the ash that is discharged from the chain grate stoker.

Some years ago we appreciated the great loss in unburnt coal thrown away in the ashes, the percentage of the combustible in the ash ordinarily running as high as 35 to 55 per cent. An attachment was designed to hold this partly burnt-out fuel in the boiler furnace after it had left the chain grate. The partly burnt-out coal was thrown over into an auxiliary furnace grate where it was kept until thoroughly burnt out, when the ashes were delivered into the ash pit by the action of a clinker bar driven from the stoker drive. Unfortunately, after two or three promising attempts this effort at improvement was abandoned.

Air Supply.

To provide a sufficient air supply under the ignition arch when a coking coal is used, the method of introducing air as shown in the illustration has been used with reasonably good success. Primarily, the introduction of air at this point was used to prevent smoke when using certain grades of coal that coke readily, and the results seemed so promising that tests were made of resultant gases, both with and without the blower. These results are as follows:

	With blower	Without blower
Draft	0.40 in.	0.42 in.
CO_2	10.4 per cent.	9.9 per cent.
O	8.4 per cent.	8.8 per cent.
CO	0.0 per cent.	0.0 per cent.

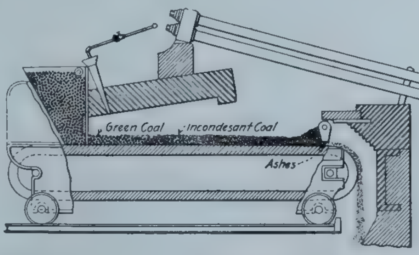
From careful samplings of the ashes discharged from chain grate stokers in a number of boiler houses, we have found that the percentage of combustible averages from 40 to 50 per cent. We think this combustible should be cut down to an average of 15 to 20 per cent.; which means in a boiler house using 50,000 tons of coal per year of 12 per cent. average ash, that there would be a saving of some 1,500 tons of coal.

Water Back Necessary.

Notwithstanding the fact that we are accomplishing a great deal by getting more uniformity in the size of the coal that comes from our crushers, we are going a step farther in providing our chain grate stoker furnaces with a water back of improved design. This water back is shown in the cut. It is hung on trunnions so that it may swing easily when large pieces of clinkers have to be discharged from the chain grate into the ash pit. Ordinarily, this water back when hanging vertically is set from 1 in. to 1½ in. above the chain grate stoker, and when coals that do not clinker badly are used, it acts as a skimmer, allowing the thoroughly burnt-out ash to be discharged into the ash pit, holding the balance of the more or less burnt-out fuel until it has time to be consumed. Results of tests on stokers equipped with this improved water back have shown a saving of 3 per cent. over stokers with the older type.

Furnace Efficiency Standard.

The standards of boiler furnace efficiencies must be established by the minimum amount of combustible left unconsumed that it is practicable to get by simple devices that will have great durability and that are effective for the particular purposes used; by the maximum possible amount of carbon dioxide without the ever-present danger of loss through lack of air supply, resulting in incomplete combustion, and a more or less high percentage of carbon monoxide and unconsumed hydrocarbons, also by a minimum radiation through the walls of the furnace itself. The best practice has shown that, when using the grades of coal mentioned, 12 to 13 per cent. of carbon dioxide and 15 to 20 per cent. combustible in the ash are good averages to strive for in continuous practice.



SCHEME FOR ADMITTING AIR AND HOLDING PARTLY BURNED FUEL IN A CHAIN GRATE STOKER.

Discussion Notes.

In the course of the discussion following the paper, Mr. Joseph Harrington said that recent experiments in quite a number of installations have developed a design of arch which he has termed the reflecting arch. This is a long inclined arch so placed that the heat from the rear or incandescent portion of the fuel bed is directly reflected to the incoming fuel at the gate. It is quite possible to place this arch so that the maximum amount of reflection shall take place. Its height and inclination, moreover, render it possible to utilize for ignition purposes, the direct radiation from the face of the bridge wall. This is no inconsiderable part of the programme, it being of the utmost value even though it may be anywhere from 9 to 12 ft. away from the gate.

Satisfactory ignition with the grate speeds up to 10 or 12 in. a minute, he said, can readily be attained, which corresponds to a rate of combustion exceeding 50 lb. per square foot. These high rates of combustion can only be attained with fuel bed thicknesses which will permit of the application of high draft. As the fuel bed thicknesses increase by virtue of increased furnace draft, greater extraction of oxygen can be accomplished, so that with other conditions the same, gas analysis of increasing merit can be secured. A high furnace draft, however, is accompanied in the usual setting by increased infiltration so that the result under ordinary conditions is not all beneficial.

Mr. Harrington expressed himself as a strong advocate of the use of recording instruments in the boiler room. The use for example of a recording draft gauge in the furnace, he said, will indicate every time the operative opens the inspection door and the time that it is open. It will tell whether or not he has allowed the fire to burn short or to acquire a bank. It will tell whether he is feeding his fuel too heavy or too light, and if this is backed up by a CO_2 chart and damper draft with a recording thermometer in the uptake, the man in the office the day after, can tell what the conditions were in his boiler room far better than he could had he lived in that boiler room through the entire previous day without the use of these instruments.

◆

The Turbine Equipment Co., Toronto, and New York, have been awarded a contract by the town of Brockville, Ont., to supply a three million gallon De Laval centrifugal pump direct connected to a 200 h.p. De Laval steam turbine, the combined unit to operate against a domestic pressure of 75 pounds per sq. inch, and to give a pressure of 110 pounds per sq. inch for fire purposes. They have also secured the order for a three million gallon De Laval centrifugal pump direct connected to a 200 h.p. Canadian Westinghouse synchronous motor for operation againts a domestic pressure of 75 pounds per sq. inch.

Boiler Deposits, Their Frequent and Thorough Removal--1

By a "Vulcan" Staff Officer *

Attention is directed in this article to the necessity for providing not only suitable apparatus for the treatment of feed water before it enters the boiler, but for unceasing attention being given through examination and otherwise to the removal of such deposits as may evade the treatment medium and find lodgement on the different interior surfaces.

EVERY boiler owner is aware of the necessity for frequent cleaning of each boiler and its surroundings, but the absolute importance of this work is not always so fully realized as it ought to be. We therefore propose to deal at some length with this question; first, as to the reasons by which such necessity arises, and second, as to the conditions under which the work should be carried out.

The most obvious reason for cleaning arises when the boiler is found to be absolutely unable to perform its required work on account of the deposit of scale inside, and of soot or dust outside the boiler and inside the flues. This condition is occasionally met with, but comparatively seldom in present practice. In any case, the neglect is attended with severe penalties, and if sufficiently powerful chimney draft or mechanical draft is available, a condition of grave danger rapidly supervenes. If it be often repeated, it is attended with speedy deterioration or practical destruction of the boiler.

The effects of wear and tear are noticeable in very different degree in separate cases where the conditions might be expected to be equal. Many reasons may contribute to affect the results, but one of the most important differences will be usually found in regard to the frequency and thoroughness of the cleaning and general attention which the respective cases receive. Neglect of this kind is invariably attended with undue depreciation and large expenditure in repairs.

Boiler Deterioration.

Notwithstanding the utmost degree of attention, boilers must and will deteriorate structurally more or less, continuously from the first day of working. It is impossible to predict either the amount or the precise character of this deterioration, and therefore frequent thorough examination is necessary in order to reveal any defects before they approach a dangerous stage. All boiler owners of repute have long arranged such examinations. The duty is, however, usually discharged by the employment of an engineering insurance company of standing and repute who specialize in this class of business.

Boiler deposit is for the greater part sparingly soluble mineral matter which has been dissolved, or other matter which is suspended in the water. This water is fed to the boiler, steam is produced, and the solid matter remains in the boiler. A very good feed water may contain about ten grains of such solid matter per gallon. If each pound of coal burnt in the boiler evaporates 8 lbs. of water ,and if the total consumption of coal per week amounts to 25 tons, then 64 lbs. of solid matter would be left in the boiler per week of ordinary work.

In good practice, an important proportion of the solid matter is removed by the judicious use of the blow-off cock, but much remains in the boiler to be removed manually when the boiler is laid off for the purpose. During periods of drought, the water contains more solids than at other times, and moreover the apparent waste of water at such times by blowing off is liable to lead to neglect, and cause accidents.

The presence of accumulated solid matter in the water is attended with increased resistance to the transmission of heat from the fuel in the furnace to the water in the boiler, and therefore with serious loss of efficiency. Such resistance, moreover, causes overheating of the plates and other structural parts, which, if continued, induces straining, grooving, and other damage by which the life and working value of the boiler are vitally affected.

Feed Water Treatment.

The solids in the water may exist as soluble matter, in which case the water remains clear, or the whole or some part may be insoluble, in which case the water is turbid or cloudy. Floating objects, leaves and grosser impurities, are removed by a strainer. If the turbidity is very intense it may be reduced by treatment in a settling tank, and finally passing through a filter, of which many designs are available for feed-water treatment.

In most of the manufacturing districts the public water supply is of such a quality that it may be used in boilers with complete confidence without treatment. In other important districts the water may not be inferior in regard to dietetic or culinary purposes, but it contains too much dissolved solid matter to be freely used in boilers without previous treatment. In some districts it has been found that the diversion of sewage from the river and the adoption of purification processes has been attended with great increase of difficulty in connection with the use of the water for boilers. As a rule waters containing up to 13 grains of dissolved solid matter per gallon may be used without treatment as regards liability to incrustration; and this allows a wide margin to the good in the majority of the waters in question. Very simple treatment may, however, be required to correct liability to cause or promote corrosion.

Water Softening Equipment.

The great majority of the substances contained in the water impart a condition known as "hardness," which in relation to domestic purposes is chiefly important because it increases the amount of soap required in connection with washing operation. The purification plant required for such elimination is usually termed a "softening plant." Many designs of such plant are available, some one or more of which may be confidently expected to successfully deal with any combination of conditions. Exhaustive treatment of the chemical principles involved in water softening cannot here be attempted, but the chief points—principally physical—may be briefly explained. These points are selected principally by way of illustration, and are not in any way exhaustive. The question is also proposed to be treated at greater length in an early issue.

The principal mineral substances to be dealt with in this way are salts or chemical combinations of bases with acids. The principal bases are the oxides of calcium, magnesium, and sodium. The salts of calcium and magnesium are sufficiently soluble in water to cause trouble in connection with a boiler when supplied with water containing them; but the sodium salts without exception possess a very much higher degree of solubility than the calcium and magnesium salts. Brine is a saturated solution of common salt, and is pumped out of the ground in salt districts. Small quantities of common salt are also occasionally found in well water in other districts. Sulphate of soda is occasionally found in large quantities in feed waters, particularly in mine waters, and sodium bicarbonate is also sometimes present.

In a commercial water-purification plant, the calcium and magnesium salts are treated by the addition of chemical re-agents, the chief of which are quick or caustic lime and sodium carbonate. The action of quicklime may be broadly described in application to a case in which one part of lime is held in solution by two parts of carbonic acid; and a second part of lime is applied in the form of lime solution or, with a less degree of accuracy, as milk of lime. The additional lime captures one-half of the acid, thereby effecting the precipitation of the whole of the lime, original and superadded. In this case the lime carbonate is removed by precipitation. Only calcium carbonate is left in solution to the extent of its solubility in water, per se. The treatment of the permanent hardness involves an exchange of acids, so as to change the lime to an insoluble condition. In other cases the action is more complicated, but in all cases the soda remains in solution and the calcium or magnesium is rendered insoluble.

---

*The Vulcan Boiler and General Insurance Co., Manchester, England.

Complete Purification Equipment.

The complete purification plant comprises apparatus for the supply of water and reagents in accurately measured proportions; also means for effecting prompt and thorough admixture of the same; space to contain the mixture under conditions of time, quiescence, and temperature, to ensure true and full completion of the required chemical reactions, a settling chamber in which the bulk o fthe solid residue is deposited; also where necessary, a filter arrangement is added for the removal of that part of the solid matter which escapes interception in the settling tank or chamber. An apparatus constructed on these lines, maintained in perfect order, and operated in accordance with the nature of the solid matters dissolved in the water will eliminate all the most objectionable constituents which are usually found in water which is available for feeding boilers.

In connection with the use of good water, purification is not required, and in the great majority of cases complete simplicity would be assured if the water could be conveyed to each works from the hills uncontaminated as is done in case of public supply. This is only possible to a limited extent in connection with private supply for boilers, and in most cases the water must be taken from the stream after having been repeatededly used, probably concentrated and rejected; also after receiving pollution in various degrees of quantity and quality. The impurities, moreover, vary from time to time, thereby causing difficulty in adjusting the reagents to accord with the amount of impurity.

Blowing Off.

In all cases boilers at work should be frequently scoured by opening the blow-off cock for such a length of time as may be required to prevent the accumulation of solid matter and soluble salts within the boiler. It is difficult to state precisely how long the cock should be kept open, but obviously this will depend upon the amount of material accumulated, as well as the frequency and the freedom of discharge through the cock and waste pipes. In any case the operation is more efficient if performed at the end of a period of banked fires, when the sediment has been allowed to collect in the bottom of the boiler, and especially in the short length of pipe which intervenes between the boiler and the blow-off cock.

Blowing-off for sediment may be stopped at any time when the water runs off in a practically clear condition. The soluble salts are, however, not in any direct way manifested; the solution is quite clear. The presence of soda may however be safely inferred when incrustation is observed at the water gauge fittings, or wherever slight exudation of boiler water is observed. At such times increased blowing down is required. It is possible that practically all the sedimentary matter may be removed by blowing down. The soluble matter is, however, uniformly distributed, and therefore can only be withdrawn in proportion to the quantity of water removed.

The term "soluble salts" is here intended to apply to all salts found dissolved in the boiler water. They may be present on account of the water used containing large quantities of salt and sodium sulphate; or as already explained they may be produced in the treatment of the water, or they may be produced in the boiler by the use of alkaline boiler compositions. A boiler of small water-capacity obviously will become fouled more rapidly than one of larger water-capacity, and therefore requires to be more frequently blown down in order to prevent excessive density.

Caustic or carbonate of soda accumulating in the boiler when exceeding 100 grains per gallon will promote priming and foaming in the boiler, whereby its economical working is prejudicially affected, and also the working of any engine to which the steam may be supplied. When it reaches 500 grains per gallon, the water attacks all ordinary brass fittings with which it comes into contact at boiler temperature.

When the amount of soluble salts reaches 1,750 grains per gallon it is of the strength of ordinary sea water as existing around the British coasts, and its presence and amount may be shown by the salinometer, which should always be used where any possibility of such amounts may exist. Pure sea water of greater strength is regularly used in marine boilers, but in the case of land boilers the accumulated solids are of miscellaneous and uncertain composition for which reason the point of danger is reached much earlier than in marine boilers. The best course is to collect samples of the water as supplied to the boilers, with special attention to the importance of average quality. These should be subjected to analysis, and the blowing-off should be done in strict accordance with the instructions of the chemist.

In a recent case, extensive damage was caused to a boiler, the feed water of which originally contained 21 grains of incrustation matter per gallon, which was reduced to 4 grains in an efficient softening plant. The original water only contained 9 grains of common salt, but a larger amount of soluble substances was produced in the chemical reactions of the process. The water contained in two working boilers was examined, and in one of these it was found that the water contained 1,500 grains of soluble salts per gallon, or about half a ton accumulated in one boiler. Other solids in the water bring the total solids up to 1,736 grains per gallon, or almost precisely the amount of common salt contained in the densest sea water around the British Islands. Unfortunately, such cases are frequently occurring, and at the moment of writing the Vulcan company has been notified of another, in which salt scale has been found in dangerous quantity.

◆

WATER FAMINE IN MONTREAL.

A SERIOUS break in Montreal's only intake pipe occurred on the afternoon of December 25, which put the low level pumping station out of commission for eight days and resulted in a very serious shortage of water all over the city. The intake is a reinforced concrete horse-shoe shaped underground conduit with a horizontal axis of 9 feet and a vertical height of 7 feet 4 inches. The break, which occurred about a mile from the pumping station, was some 60 feet in length. General opinion as to the cause of the break places the blame on certain excavation work that was being carried on close to the conduit.

Before the conduit was built, about five years ago, the city's water was brought to the pumping station by an open aqueduct. The concrete conduit was commenced in 1908 on the recommendation of Mr. Geo. Janin, the present City Engineer, the object being to avoid contamination of the water. In 1910 work was commenced on the enlargement of the old aqueduct with a view to obtaining a further supply of water for industrial and power purposes. This work had only been completed a short time, when further enlargement was decided upon and is still being carried out by the Cook Construction Co. The aqueduct runs parallel to the conduit and in its enlarged cross-section approaches the latter very closely.

First Sign of Trouble.

About the middle of December the conduit was found to be leaking badly, due apparently to the removal of aqueduct support by the surrounding soil, as a result of the adjacent excavation work. The conduit, at the point where the leakage occurred, was uncovered, and the cracks were caulked. It was then attempted to give proper support to conduit by driving sheet piling and packing in stone filling. This work was completed on December 23, but proved merely a temporary expedient; for as above stated a disastrous break occurred at about 5 p.m., December 25 and the pipe quickly emptied itself.

At the time of the break Montreal's upper level reservoir was only half full, and but for the help of the Montreal Water & Power Company, a corporation which supplies certain of the surrounding districts, the city at the end of a very few hours would have been absolutely without water. The above mentioned company were able to supply about 15,000,000 gallons per day, but the city's normal daily consumption is about 50,000,000 gallons; so that very serious loss and inconvenience were caused, especially in the uptown district. Before the service was restored sanitary condition had become serious and the ever present danger of a huge fire kept the public in an extremely nervous state of mind.

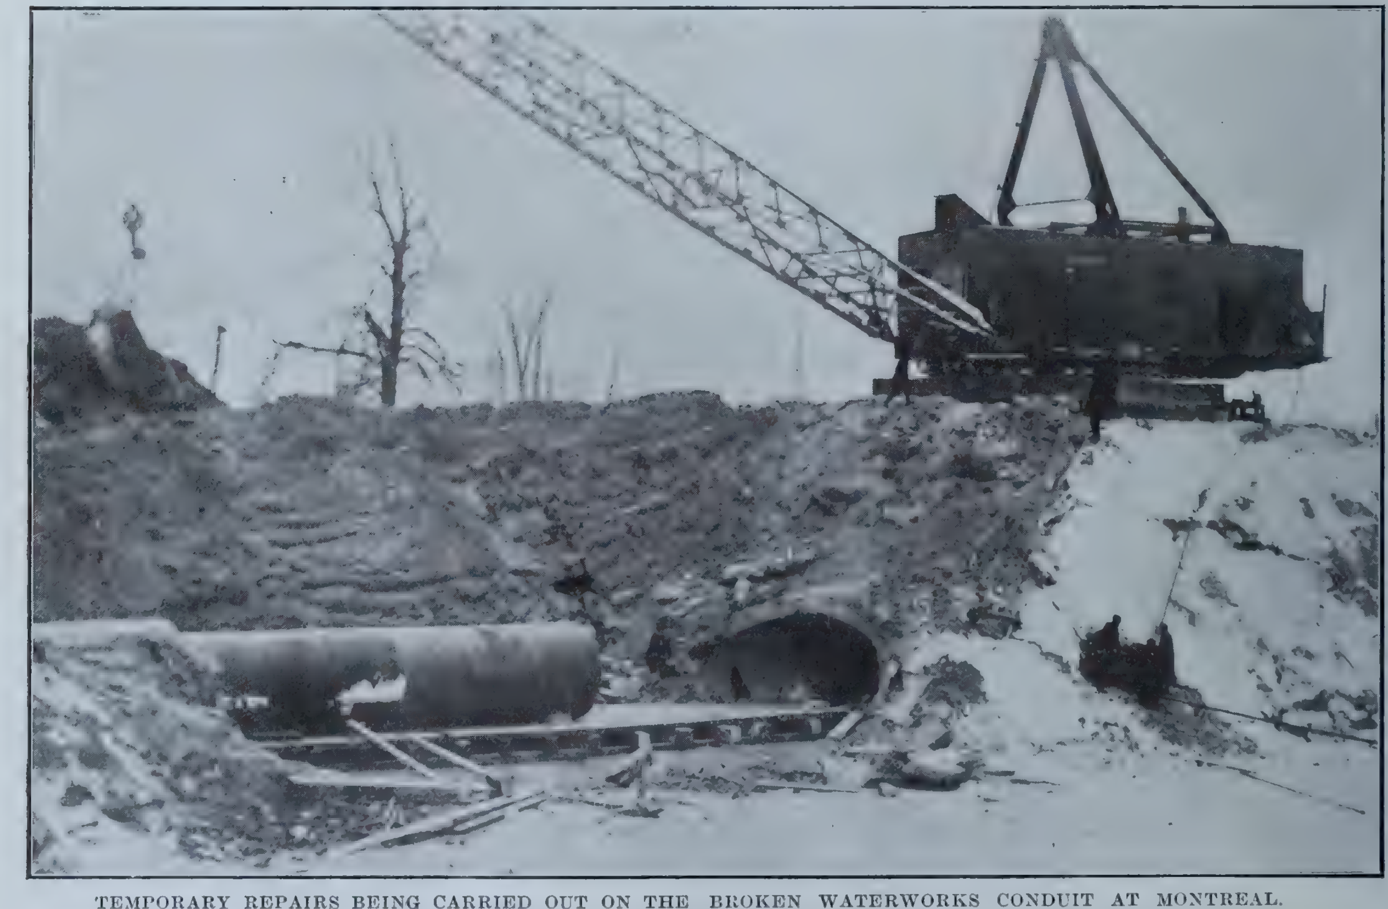
Repairing the Break.

As soon as the break was discovered, a gang of men was collected and the work of repair commenced. A rush order was placed with the John McDougall Caledonian Iron Works Company for seven lengths of steel tube 7 feet in diameter, each length to be 18 feet long with an angle iron jointing ring at each end. The first operation to be performed was the removal of the burst section of the conduit, which was to be replaced by the steel tube. For this work a drag line excavator, which had been working on the adjacent aqueduct and had very possibly caused the original damage, was brought into requisition. The length of conduit removed was 62 feet, so that the seven lengths of pipe, when bolted up, gave a lap at each end of 32 feet. The space between the outside of the pipe and the walls of the conduit was then filled in with bricks dipped in bitumen, concrete being also poured in by means of holes bored through the top of the conduit. Early on the morning of December 31 the pumps were started up once more, but had to be promptly stopped again as the leakage at the steel pipe was found to be very serious. This necessitated the emptying of the conduit again and sealing up of the joint more carefully. The concrete was given 30 hours to set and the timber staging supporting the steel pipe was strengthened. These steps proved effective and by the early morning of January 3 there was once more full pressure all over the city.

Needless to say public opinion was greatly exercised over the calamity, which is unprecedented in the history of Montreal, or probably of any city of like size. Had the break occurred during the summer the results would have been infinitely more serious, and steps are now being taken to prevent a repetition of the water famine by running a steel pipe 1,200 feet long from the pumping station to the Lachine canal. This, of course, will only be used in emergency, as the water so obtained would not be all that could be desired for drinking purposes.

◆

John R. Freeman, who has been engaged as an expert to inquire into the water situation in Montreal, was born in 1855, and received his early training as an engineer with the Essex Company of Lawrence, Mass., of which the late Chas. J. Storrow, one of the earliest and most able of hydraulic engineers in America, was the executive head. After acting as consulting engineer to various manufacturing companies, Mr. Freeman opened an office in Boston.



TEMPORARY REPAIRS BEING CARRIED OUT ON THE BROKEN WATERWORKS CONDUIT AT MONTREAL.

ELECTRICITY AND HYDRAULICS

This department is intended, in addition to individual treatment, to feature the close relationship existing between electricity and hydraulics in the power and light field.

MECHANICAL DIFFICULTIES IN ELECTRICAL DRIVES.

THE standardization of electrical machinery has now reached such an advanced stage that there is a very great temptation for those who have not thoroughly considered the matter to regard the installation of electric power as simply the question of putting down a plant in the most convenient spot and attaching the motor to it in the quickest and simplest manner.

While this point of view has a good deal to recommend it, it should never be forgotten that unless adequate precautions are taken in connection with the mechanical position of the drive, there is a certain amount of trouble which will develop, more particularly if the installation is subjected to any abnormal conditions of heating or similar causes, and it will, therefore, be worth while mentioning one or two cases where trouble has occurred in connection with the mechanical portion of electrical drives.

It may be said that the instances mentioned are derived from experiences in connection with electrical plant in the tropics, and, therefore, the conditions under which the plant was operated may be somewhat more severe than is usually the case; but even taking this into consideration, the principles underlying the notes are identical with those obtaining in ordinary everyday practice, and are, therefore, of a fairly wide interest.

Extremes of Temperature.

Where temperature conditions are at all extreme it is very frequently found that considerable trouble is experienced in connection with the bearings, and very hot bearings are quite common on generators and motors in tropical climates. Where much care is not taken to avoid overheating, it will be found that the high temperature of the enclosure in which the motors are placed, combined with the development of heat from the windings, causes the oil, even if this be of a heavy nature, to be always in a condition approaching boiling point, and it is not an uncommon experience to find that, after a run of about three days, the bearings, unless they are watched for the purpose, will fire.

This is caused by the fact that owing to the high temperature to which the oil is exposed, the nature is rapidly drawn out of it, and on more than one occasion it has been discovered that firing has taken place in this way, and when the bearing has been opened up, the shaft has been found to be covered with a deposit not unlike a layer of shellac varnish. The same kind of deposit is also found along the edges of the brasses, and, when this kind of deposit appears, the shaft is liable to run very dry and fire almost immediately.

The only way to get over trouble of this nature, providing the best oil obtainable is being used, is to carefully watch the bearing and to carefully time the machine. After, say, about 2½ or 3 days running time, the machine should be shut down, the oil well emptied and thoroughly cleaned out, and the oil changed. If caught in time, no damage is done to the shaft, and providing that at each change of oil the bearing surfaces are well cleaned with paraffin or kerosene, the difficulty alluded to can be satisfactorily overcome. It will be seen that this requires unremitting attention on the part of the motor attendant.

Ball Bearing Remedy.

This is by no means a fictitious trouble, and, as a matter of fact, in tropical climates most generator and motor bearings give a lot of trouble in this way and require so much supervision that it is now found a very useful practice to employ, instead of plain white metal bearings, ball-bearings in order to avoid breakdown. These ball-bearings have been found to be most useful in connection with motors of small and medium sizes, as they will run with graphite lubrication in a very smooth and satisfactory manner for long periods, but they are not quite so good for the bearings of large main generators, inasmuch as the bearing loads for such purposes are so heavy. Thus, in such cases, the best way of modifying the difficulty referred to in the previous paragraphs as far as possible is to instal with the bearings an efficient system of water-cooling, so arranged that a free and ample stream of as cold water as possible can be continuously maintained in intimate contact with the shell surrounding the actual bearing surface. If this is thoroughly well attended to, it will be found that bearing difficulties due to overheating will be largely avoided.

Care of Belt Drives.

Another thing which requires considerable attention where motors drive a plant by means of belts, and not by spur or other rigid systems of gearing, is to see that the belts receive proper treatment. There is very great danger, especially in tropical climates, that if a belt is allowed to run without ample periodical attention, it will become dry and slip.

The average attendant then seeks to overcome the difficulty by tightening up the belt to stop the slipping, and this proceeds until the strains upon the belt and pulleys are altogether in excess of those which should normally occur, bringing about in time inevitable damage. On the other hand, the use of belt dressing to keep the surface of the belt in a pliable and clinging state while extremely useful, should only be adopted in moderation.—The Power User.

* * *

INTERESTING EXPERIMENTS.

EXPERIMENTS have been carried out to ascertain the danger from electric shock in directing a stream of water on a high-tension electric line. The resistance of a stream of water between the nozzle of a hose and a 12 ft. length of No. 6 copper wire was measured. Energy was obtained from a 250,000-volt 50-kilowatt transformer, with the middle point connected by a low-reading ammeter to earth and one terminal connected to the line. Variations of frequency between 45 and 60 cycles with 20,000 volts showed no appreciable reactance of the stream; resistance was calculated from current and voltage readings. The resistance of the stream rose with increase of water pressure, being slight for 6 ft. to 10 ft. lengths of streams, but marked for 15 ft.

With a 1 ⅛ in. nozzle for 5,000 and 30,000 volts, critical lengths of stream were found up to which the resistance had a gradual increase, these being 17 ft. for a 1⅛ in. nozzle, and 20 ft. for a 1½ in. With a stream length of 15 ft. on a 50,000-volt line, a resistance of about 20,000 ohms water path was obtained, giving a current of about 0.25 amp. This would give the holder of the nozzle a severe shock and might be dangerous. With a stream length of 20 ft. for a 1⅛ in. nozzle, or 25 ft. for a 1½ in. nozzle, the resistance was 800,000 ohms. This might be painful but practically not dangerous. The resistance of the body, being relatively low, is neglected.

The fact that a nozzle is earthed through the stream of water in the hose was not found to eliminate danger to the nozzle holder. The resistance of this path from nozzle to earth, through the water in the hose when the latter was thoroughly insulated from earth, was found to be about 150,000 ohms per 100 ft., which could not be depended upon to shunt much of the current from the man holding the nozzle.

◆

WATER RAISING AND MEASUREMENT.

In a paper read before the Association of Engineers-in-Charge, Mr. W. H. Booth dealt with water-raising and measurement. Water-raising, omitting primitive machines, he stated, is carried out by means of machines which may be classed in six divisions, represented by the scoop wheel, the displacement rotary pump of the gas exhaustion or similar type, the centrifugal pump and the bucket pump, which may be made either with a bucket, a plunger, or both, or with many buckets on a chain run continuously up a pipe; by the air-lift pump, or, as a class alone, the Humphrey gas pump, in which the duties of the pistons of both the pump and the actuating gas engines are filled, and well filled, by the water to be raised.

Needless to say, water-raising is done under so many conditions that considerable judgment must be used in selecting the machine proper to each condition. Under very heavy pressure the bucket of a reciprocating pump takes the form of a ram. The extreme case is the small ram of the pump of an hydraulic press. The more moderate case is the boiler feed pump.

The scoop wheel is a very low breast water wheel reversed, and, as such wheels may be seen in Holland, where they are found in lifts of about 4 ft., they are very efficient machines for lifting much water to a moderate height, and are thus employed to freshen up the Amsterdam canals—that is to say, to remove the stagnant water when the canals are supplied with clean water from the sea or some land drain. The scoop wheel is large and slow of movement, and is thus a very safe machine. It is simply a low breast wheel of which a few degrees of arc of the lower part of the wheel runs a close fit in a circular breast of masonry. The floats are not radial, but so inclined from the radius that the edges somewhat face the stream to be raised and discharge at a convenient angle on the upstream side of the low lift. This is done so that the water in dropping out of the wheel gives a minimum of back pressure.

MY FUTURE—A CREED.

By H. F. Frasse.

I KNOW that my future depends upon myself, because the manner in which I perform the duties assigned me will determine my value.

I shall always give a heaping measure, that my pay may be in proportion to the service I render.

It shall be my aim to work for, talk for, and boost my employer, because I am one of the organization.

Under no circumstances shall I listen to or take part in discussion affecting hurtfully the welfare of my employer.

I believe that every man will find if he look carefully into his own work that he has an undiscovered character for good; as well as that he possesses loyal service to give his employer.

I know there is no substitute for thorough-going, ardent and sincere earnestness, nor does it come of its own volition. It must be considered and made positive in each man's mind.

I am convinced that one man is better than another according to the quality, more than the quantity, of work he performs.

I shall always be cheerful with my associates and outsiders, because cheerfulness is contagious, lightens the work and brings credit to my concern.

Light hidden under a bushel is seen by no one, hence is of no value in making comparisons.

I shall let my light so shine that all men may see my good work and benefit thereby.—N.E.L.A. Bulletin.

RECENT IMPROVEMENTS IN WELDING.

A LECTURE was recently given before the Birmingham Metallurgical Society by Mr. Alex. E. Tucker, F.I.C., on "Recent Improvements in Welding," in which the conditions for successful welding were discussed. Mr. Tucker showed that the thermit process, in which aluminium powder was used, was of great use in the Russian-Japanese war, and had been the means of repairing extensive damage done to the Russian fleet. The replacement of acetylene by hydrogen in the cutting and welding of steel was also discussed. Mr. Tucker pointed out that the difficulties of making successful welds with acetylene in the case of parts of engines and machines was very great. There was always the risk of carbonization on the one hand and oxidation on the other. This was not the case when hydrogen was used, and modern practice showed the reality of these objections.

◆

ICE TROUBLE OVERCOME.

THE water-wheels of The E. B. Eddy Co., at Hull, Que., are practically the only ones at the Chaudiere not shut down or hampered on account of anchor ice. Mr. Millen of The Eddy Co. appears to have solved the problem of anchor ice, and found the way to prevent it forming on the racks of the intake.

When the Eddy Company decided to more than double their old water powers by putting in new wheels and new systems, and converting the whole into a Hydro-Electric plant, Mr. Millen had the entire fore-bay covered with a concrete platform—put two fans under this platform, and one fan inside, near the clear storey roof of the No. 1 paper mills. These fans exhaust all the steam and hot air from the paper mill, expel it into the vacant space over the water and under the flooring of the fore-bay. This keeps the temperature at the racks just sufficiently warm to prevent ice forming on the racks.

C. C. Cariss, chief draughtsman for the Leonard Engine Works, London, Ont., has been appointed instructor in mechanical drawing and shop mathematics for evening classes, at Ingersoll, Ont.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent practical questions, and give same, direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

Question.—A system of pulley blocks is used to lift a weight of three tons, and if the number of sheaves in the blocks are such that 16 feet of slack is gained for every foot the weight rises, what power will be required if friction be neglected?

Answer.—Three tons is equal to 6,000 pounds; therefore, the pull required will equal $\frac{6000\times1}{16}$ or 375 pounds.

* * *

Question.—A mechanic exerts a pull of fifty pounds at the end of a three-foot spanner, and the nut which he is tightening has a pitch of four threads per inch; if friction be neglected, what stress would he bring to bear on the bolt?

Answer.—Let us suppose a revolution to take place, then the end of the lever in the operator's hand would pass through a space which is the circumference of a circle whose radius is three feet, while the nut would move ¼ inch. The circumference corresponding to 3 feet is 226 inches, therefore, the ratio of motion is 226 to .25 $=\frac{226}{.25}=904$ to 1, and the stress on the bolt being tightened, would equal $50\times904=45{,}200$ pounds.

* * *

Question.—A pressure of 10 pounds acts at one end of a system of levers, and it is found that if motion were to occur, the end where this pressure acts would move through a space 40 times as great as the other end. What pressure would be exerted on the latter?

Answer.—The motions are 40 to 1 and, since the pressures are inversely as the motions, the pressure required would equal $\frac{10\times40}{1}$ or 400 pounds.

* * *

Question.—A balance weight attached to the crank of an engine weighs 4,000 pounds, and the distance where its mass may be supposed to be concentrated is 1½ feet from the centre of the shaft; the revolutions are intended to be 120 per minute, and two is the number of bolts determined upon to secure the balance weight. What should be the size of the bolts if they are of 62,720 pounds tensile strength, and with an assumed factor of safety of 10?

Answer.—The circumference of 1½ feet radius is 9.427 feet; therefore, the circumferential velocity at 120 r.p.m. will be $9.427\times120=1{,}131$ ft. per minute, or 18.85 ft. per second. The centrifugal force or tension on the bolts will be $\frac{4{,}000\times18.85^2}{32\times1.5}$ or 29,527 pounds, which is 14,763 pounds to each bolt. As the tensile strength of the bolt material is 62,720 pounds and the factor of safety 10, therefore $\frac{14{,}763\times10}{62{,}720}=2.35$ square inches area at the bottom of thread, equivalent to 2⅛ in. diameter and 4½ threads per inch. The figure 32 used in the calculation is the acceleration due to gravity in feet per second.

* * *

Question.—Express by means of a formula how the dead load at the pitch circle of a gear wheel to transmit the required power is computed.

Answer.—Multiply the horse-power to be transmitted by 33,000 and divide by the velocity of the pitch circle in feet per minute. Example, if the horse-power to be transmitted is 500, and the pitch circle velocity be 2,000 ft. per minute, then $\frac{500\times33000}{2{,}000}=8{,}250$ pounds, or the maximum load at the pitch circle.

* * *

Question.—A feed pump has to discharge 1,925 pounds of water per minute against a pressure of 90 pounds per sq. inch, and the area through the valves is from restricted discharges, etc., what 2 sq. inches; neglecting friction and loss would be the horse-power required?

Answer.—Since the fluid is water, the head corresponding to 90 pounds pressure equals 90×2.31, or 207.9 feet. The discharge per second will be $\frac{1{,}925}{60}$, or say 32 pounds, and since a cubic inch of water weighs .036 pounds, the discharge will equal $\frac{32}{.036}$ or 900 cubic inches per second. Also, since the area through the valves is 2 sq. inches, the velocity will be $\frac{900}{2}$, equal to 450 inches per second, or 37.5 feet per second, and the head necessary will be $\frac{37.5^2}{64}$ or 22 feet. The total head required equals 22×207.9, say, 230 feet, and the horse-power will be $\frac{1925\times230}{33000}$ or 13.4

* * *

Question.—Steam is expanded to 10 pounds absolute pressure, and it is desired to have the feed water at 130 degrees, the temperature of the injection water being 86 degrees, how many pounds of injection water, per pound of steam condensed, will be required?

Answer.—The total head of steam at 10 pounds absolute is 1172.3 thermal units, therefore the ratio required is $\frac{1172-130}{130-86}$, or 23.7 to 1. The common allowance for engines with surface condensers is 24 to 30 times the weight of steam condensed, and for engines with jet condensers, from one-third to one-half the cylinder capacity.

* * *

Question.—Why do the driving wheels of a locomotive frequently slip at starting, and how does the application of sand overcome the difficulty?

Answer.—If the tractive force exerted by the locomotive exceeds the frictional resistance at the rails due to the adhesion of the driving wheels, then the wheels will slip. The resistance to slipping varies with the condition of the rails, and is greater when they are dry or wet than when they are merely damp. The application of sand to the rail, of course, increases the friction and enables the driving wheels to obtain a grip. To avoid slipping, the tractive force should not exceed about 22 per cent. of the weight on the coupled wheels.

* * *

Question.—A bucket conveyor driven by an electric motor is used for lifting coal from a railroad car to a hopper 50 feet above the car. If 40,000 pounds of coal are raised per hour, find the horse-power of the motor. Assume the combined efficiency of motor and conveyor to be 60 per cent.

Answer.—$\frac{40000\times50}{60}=$ foot-lbs. of work done per minute. Since the efficiency of motor, etc., is only 60 per cent., the horse-power required will be

$$\frac{40000\times50\times100}{60\times33000\times60}=16.83\text{ h.p.}$$

Question.—A safety valve is 3 inches in diameter; the lever is 24 inches long and weighs 15 pounds, its centre of gravity being 13 inches from the fulcrum. The weight of the valve and valve stem is 12 pounds, and the centre line of the valve is 4 inches from the fulcrum. If a weight of 70 pounds is hung on the end of the lever, at what pressure per square inch will the valve commence to blow off?

Answer.—First calculate the area of the valve, thus $.7854\times3\times3=7.068$ sq. in. The forces holding the valve down on its seat are three in number:

(1)—The weight, 70 lbs., multiplied by its 24 inches distance from the fulcrum.

(2)—The weight of the lever, 15 lbs., multiplied by the 13 ins. distance of its centre of gravity from the fulcrum.

(3)—The weight of valve and stem, 12 lbs., multiplied by their distance, 4 ins., from the fulcrum.

The above three moments act downwards, and their sum must be equal to the upward moment due to the total pressure on the valve, multiplied by its distance, 4 ins., from the fulcrum.

Call the boiler pressure P pounds per square inch. Then

$$P\times7.068\times4=(70\times24)+(15\times13)+(12\times4)=P\times28.272=1680\times195\times48=1923$$

$$P=\frac{1923}{28.272}=68 \text{ pounds.}$$

* * *

Question.—To what strain is the shell of a steam boiler subject?

Answer.—To a tensile or tearing apart strain in the girth direction of the plate. For this reason we use the ultimate tensile strength of the material, in calculating the working pressure permissible.

* * *

Question.—If you were specifying the steel for boiler shell plates, what qualification would you make in respect to thickness and quality?

Answer.—That each be uniform, providing equal wear and strength throughout.

* * *

Question.—Is the shell of a boiler equally strong longitudinally and circumferentially?

Answer.—No, it is twice as strong in the latter direction as it is in the former.

* * *

Question.—In a new, well-designed, well-constructed boiler, where is the shell weakest?

Answer.—Along the riveted joint, due to the rivet holes.

* * *

Question.—Why is a butt joint preferable to a lap joint in a steam boiler?

Answer.—Because it avoids offsetting the plate ends, keeps the shell in a true circle, and gives a stronger joint.

* * *

Question.—What is the objection to welding the longitudinal joints of a boiler shell?

Answer.—No guarantee can be had of the reliability of a weld. The pressure being internal and bursting, would tend to aggravate any imperfection, and open the weld, causing an explosion.

* * *

Question.—What is the difference between a tube and a pipe?

Answer.—A tube is indicative of surface, a pipe of area. Example—A 3-inch tube will measure 3-inch outside diameter, while a 3-inch pipe will measure 3-inch inside diameter.

* * *

Question.—Are two 4-inch pipes equal in area to one 8-inch pipe?

Answer.—No. The 8-inch has an area double that of two 4-inch pipes. Doubling the diameter, therefore, increases the area fourfold.

WEDGES, SCREWS AND SCREW JACKS.

By H. Womersley.

THE wedge is a double inclined plane, hence when two bodies are forced asunder by its means in a direction parallel to its head, by multiplying the resistance by half the thickness of the head or wedge back, and dividing the product by the length of one of the inclined sides; the quotient is the force equal to the resistance.

Example.—The breadth of the back or head of the wedge being 3 in., and its inclined sides 10 in., required the power necessary to act upon the wedge to separate the substances whose resisting force is 150 lbs.

$$\frac{150\times1.5}{10}=22.5 \text{ lbs.}$$

When only one of the bodies is moveable, the whole breadth of the wedge is taken as the multiplier, and the following rules are for such wedges acting under pressure on the head of the wedge only.

To find the tranverse resistance to the wedge or weight; multiply the power by the length of wedge, and divide by the breadth of the head.

To find the power: multiply the weight or tranverse resistance by the breadth of the head, and divide by the length of the wedge.

To find the length of wedge; multiply the weight by the breadth of the wedge, and divide by the power.

To find breadth of wedge: multiply the power by the length of the wedge and divide by the weight.

The Screw.

The screw in principle is that of an inclined plane wound around a cylinder which generates a spiral of uniform inclination; each revolution producing a rise equal to the pitch of screw. The pitch being the height or angle of inclination, and the circumference the length of plane, when a lever is not applied; but a lever being a necessary qualification of the screw, the circle which it describes is taken, instead of the screw circumference as the length of the plane; hence the mechanical advantage—as the circumference of the circle described by the lever where the power is applied is to the pitch of the screw, so is the force to the resistance.

Example I.—Required the effective power obtained by a screw ⅞ in. pitch, and moved by a force equal to 50 lbs. at the extremity of a lever 30 in. long.

$$\frac{30\times2\times3.1416\times50}{.875}=10760 \text{ lbs.}$$

Example II.—Required the power necessary to overcome a resistance equal to 7,000 lbs. by a screw 1¼ in. pitch and moved by a lever 25 in. long.

$$\frac{7000\times1.25}{25\times2\times3.1416}=55.73 \text{ lbs.}$$

The Screw Jack.

To find the weight a screw jack is capable of lifting, the screw being ½-in. pitch, radius of handle 30 in. and force applied 40 lbs.:

$$\frac{40\times30\times2\times3.1416}{.5}=15{,}080 \text{ lbs.}$$

FAMILIARITY BREEDS CONTEMPT.

AN inspector going through a plant in Illinois observed a set-screw projecting on a revolving shaft. He considered it particularly dangerous because the shaft was near a passageway and workmen were continually going back and forth past it. He called the manager's attention to it. "Don't you think," he said, "that that set-screw had better be cut off? Someone will get hurt some day if it is left that way." "I don't think so," the manager replied, "that set-screw has been like that for years. No one has ever been hurt by it. The fact that it is exposed and can be observed by anyone renders it safe from causing an accident." This manager had a habit of gesticulating when speaking, and, as he waved his arm to emphasize what he was saying, the sleeve of his coat came in contact with the set-screw and caught on it, and in an instant he was whirled to death.

THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

COMPETENCY OF STATIONARY ENGINEERS.

By Harry Dickinson.

IN the December issue of The Power House W. Hoxtable has an article entitled "Letting in the Light." Mr. Hoxtable speaks of what he has seen some stationary engineers do. One put eight pails of water in the boiler, closed it up, and then finished pumping with injector. Now, Mr. Editor, does that look reasonable? What size was this boiler? He did not say. He also speaks of boiler inspectors being appointed with only two years' experience. Let me say that it takes a man with hard brains to fill a soft position, and if the inspector was not capable, he would not be appointed.

Mr. Hoxtable also speaks of the graded certificate. I can see nothing wrong with the one which the Government now gives out. Graded certificates will not keep the boiler clean. Let the boiler inspector or the factory inspector have a little to say about the certificates. You will find lots who call themselves first-class men who could do more on paper than they could on actual plant operation.

* * *

REORGANIZING THE BELTING DEPARTMENT. OF A MACHINE SHOP.

By H. Womersley.

ABOUT three years ago I took charge of a machine shop and was told that any improvements I wished to introduce would be welcomed. I can assure you there was plenty of scope. The belting was in a deplorable condition, so I decided to tackle it first, and what follows is an outline of how I proceeded to bring this important equipment to a proper state of efficiency.

I entrusted the care of all belts to one man and held him responsible for all repairs, alterations and dressings. Notices regarding this were posted throughout the shop. The belt man was supplied with the necessary tools, which consisted of clamps and rods, belt scraper, knife sharpener, awl, drive punch, blind punch, staple puller, pegging hammer, brush for compound, etc.; also a compound for preserving leather belts made from the following:—Two quarts castor oil, 1 lb. tallow, 1 oz. powdered resin, 2 oz. hard soap, melted and mixed together.

I next instructed him as to how I wanted the belts repaired and cleaned, and informed him that he must make a careful inspection of all belts at frequent intervals and keep a record of same. His inspection must cover such points as general condition, whether overdry, or saturated with oil; whether any laps had begun to start open, or whether a belt needed early replacement.

If the belt were dry or harsh he was to first clean off the surface dirt, this being accomplished by means of a cloth, damped in kerosene, if need be. In bad cases, the belt was to be scraped; the ideal aimed at being a clean leather surface. A light application of dressing was to follow. For greasy belts, wiping on the pulleys with a dry cloth or some absorbent material would help, but, if possible to remove the belt, packing in dry sawdust or shavings was recommended for the purpose of absorbing the oil. An excess of oil, it should be explained, tends to rot the leather.

Jointing Belts.

I next instructed him on jointing belts, and as I have a fancy for the "hinge" style, I showed him how to make that joint as follows:

Cut the ends of belt to be joined perfectly true with a tee square.

Punch two rows of holes in each end of the belt, care being taken that the holes are not opposite each other, and that one of the ends contains one more hole than the other.

No hole should be less than ½ in. from the edge of the belt, and no nearer than ¼ in. to the end. The second row must be 1 in. from the end alternate with the first row. A good rule is as follows:—

2 in. to 2½ in.	3	holes.
3 in. to 4 in.	5	"
5 in.	7	"
6 in.	9	"
8 in.	13	"
10 in.	15	"
12 in.	17	"

Width of Belt Lacing.

Up to 5 in.—¼ in. and 5-16 in.
6 in. to 14 in.—⅜ in. and ½ in.
14 in. and over.—⅝ in.

Begin to lace by drawing half the lace through the centre hole. If you commence with the upper end of lace, pass it over the one, and under the other end of belt, and continue in this way, over and under until the last hole is reached; then fasten your lace in the usual manner. When you commence to lace with the lower half of lace, follow same method, except that you pass the lace under the one and over the other end down through the hole from the opposite side of belt. Both sides of belt show lacing to be alike. This plan of lacing produces pliable joints.

Next avoid putting on belts too tight. The proper tension is of fundamental importance. If too tight, there is a large unnecessary loss of power from excessive friction. On the other hand, if too slack, the belt is liable to flop around and jump off the pulleys when a load is suddenly thrown on and off.

I also pointed out to him that single belts should be put on to run with the grain or hair side, next to the pulleys, and so that the joints of the laps run against the pulleys, as the laps on the outside of a belt are most liable to come apart when the joints are run against the atmospheric pressure. Double belts should be put on so that the points of the laps run with the pulleys, as both sides point in the same direction.

Belting Rules.

I wrote him out the following rules regarding belting:—

To find the Velocity of Belting—Multiply the diameter of the pulley in feet by 3.1416, and again by the revolutions of the pulley.

To Find the H.P. of Belting—Multiply the velocity by the width of the belt in inches, and that product by 50 for single, 80 for double, and by 100 for three ply. Divide this product by 33,000 and the quotient will be the H.P. which a good belt can safely transmit.

To Find the Width of Belting—Multiply the given H.P. by 33,000, and divide this product by the product of the velocity multiplied by 50 for single, 80 for double, and 100 for three ply.

To find the length of belts when it is inconvenient to use a tape:

(a)—When both pulleys are of about the same size. Add the diameter of the two pulleys together; multiply this result by 3.1416, and divide by 2. To this quotient add twice the distance between centres of the shafts, and this will give the required length.

(b)—When one pulley is considerably larger than the others. Square the distance between the centres of the shaft; add to this the square of the difference between the radii of the two pulleys, and from this total extract the square root and multiply by 2, thus acquiring the total (M). Add the diameters of the two pulleys together and multiply this total by 3.1416, then add to one-half of this result the total (M), and you get length required.

(c)—For cross belts.—Square the diameter of the large pulley and the distance between centres, add together and extract square root. Square the diameter of the small pulley and the distance between centres; add together and extract square root. To the sum of the two roots, add one-half the circumference of the two pulleys, when the total will be the required length.

I must confess here that this beltman turned out to be a very good man, for after this system had been in operation two years, the principal of the firm made this statement to me:

Your system of belt repair is a great success, because it minimizes machine stoppages, the leather bill is going down, less repairs seem to be necessary to shafting, also, the appearance of belts repaired in a uniform manner is not an eyesore as formerly.

◆

SETTING OF VALVES.

By "Staveley."

SIMPLE eccentric.—Set the crank on one of the dead centres, turn the tumbler of the eccentric round to get the required lead, and, having clamped the tumbler, pull the engine over to the other dead centre. If you get the same amount of lead, the tumbler is properly set on the shaft, but if the lead be greater at one end than the other, either the valve rod or the eccentric rod is too long or too short. It is very important to see that the rods are of the right length before attempting to set the valve correctly.

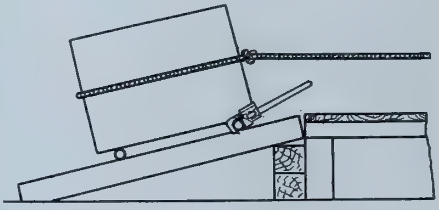
Link Motion.—Set the tumbler roughly in the right position on the shaft, put the reversing lever into full gear, back or front, and see what clearance you have at the top or bottom of die, when the engine is pulled round. Alter the length of the reversing rod to make the clearance equal at the top and bottom, then, keeping the reversing lever in full forward or backward gear, pull the engine round in order to see if the port opening is equal at both ends. If it be not equal, then the eccentric rod or the valve rod is too long or too short. Pull the reversing lever over to full gear in the opposite direction and try again if the port openings are equal. If on both occasions it is found that both rods are either too long or too short, then the valve rod requires altering, but if in one gear the rods are found to be too long, and in the other gear they are found to be too short, then one eccentric rod must be shortened and the other lengthened.

◆

MOVING HEAVY OBJECTS.

By D. S. Mann.

IN moving heavy materials, such as machinery, marble, etc., where rollers are used on wooden timbers, the rollers are found to sink into the wood slightly and often sufficiently to practically prevent the movement. Where a block and tackle is used for pulling, it will often be found that the object will slide on the rollers before they will turn. In such cases it will greatly expedite matters if a pipe wrench is put on each end of the roller and used to propel the same. The results will be surprising and two men with ordinary pipe wrenches can walk a tremendous load up a good incline without any trouble. Of course, some means should be provided to hold the load. The rollers having such a short radius, the leverage gained is great and the action is the same as that of a self-propelled vehicle.



MOVING HEAVY OBJECTS.

◆

Winnipeg, Man.—The National Construction Co. have applied for a permit to erect a power house for the Provincial Government to supply power to the Parliament Buildings, Law Courts, etc. It will cost $160,000. The boiler room will contain fourteen boilers. There will also be an engine room, workroom, fan room, and pump room. A smoke consumer will be installed.

LOCATING LOSSES IN BELT TRANSMISSION.

By C. T. R.

THE factory superintendent who knows his business is constantly seeking new ways of overcoming loss of power in belt drives. Every belt in a factory drops some power which has been paid for but never received at the final point of application. This loss may run from a nominal amount up to fully half of the actual power delivered at the drive pulley. Efficient production demands that this loss be reduced to a minimum. How to do it is an important study.

Given pulleys of the correct diameter and width, and the proper speed for the machine in question, the greatest loss occurs through slipping or binding of the belt. Dry, hard belts running over slippery pulleys either waste a vast amount of power through slipping, or they have to be drawn so tight that they waste a correspondingly great amount of power through friction. Belts should be run loose and they should be kept in such a natural soft condition that they grip the pulley surfaces firmly without the use of sticky belt dressing.

There is another point where a great loss of efficiency occurs and this is at the joint or lacing, for unless the joint be smooth and flexible, it requires considerable extra power to drive it over the pulleys. A stiff joint works like a street car with a flat wheel, and a joint with an offset or bump on the pulley side may be compared to a wagon wheel passing over a stone on a smooth pavement. Both produce a jerk and both use up unnecessary power.

It has long been known that belts laced with leather lacing are open to the latter criticism, and, furthermore, leather lacings break oftener and take much longer to do than the modern steel lacings. A good steel lacing is superior to leather lacing in durability and saving of time, but the character of the steel lacing should be carefully investigated before a choice is made. The metal lacing must be strong and it must be as flexible as the belt itself. It It should be quick and simple in application, proof against rust and corrosion, and the points of the metal which enter the end of the belt should be so made that they divide the strain evenly and do not cut off any of the belt fibres, for this weakens the belt.

Some metal belt lacings have been very severely condemned by safety authorities because the prongs work loose and catch the clothing or hands of the machine operators, yet this cannot occur where these prongs point back toward the end of the belt and are sunk in flush with the surface.

TENSION ON CYLINDER COVER STUDS.

By J. H. Rodgers.

IN the September, 1909, issue of The Power House a question of steam pressure was brought before the readers, and, after having been discussed for three or four months, the matter was shelved. With a view to reopening the discussion, I beg to submit the following:

The Original Query.

The question as originally stated by Mr. Jones was as follows:—If we had a cylinder cover secured to the cylinder by ten studs, each screwed up to a tension of 1,000 lbs., and if the face of the cover has an area of 100 square inches in contact with the steam, would there be an increased tension on the studs if steam were admitted into the cylinder at 80 lbs. per sq. in.? Mr. Jones thinks there would be no increased tension until the pressure in the cylinder exceeded 100 lbs. per sq. in., and, while I do not agree with him or other readers with a similar theory, I am open to conviction. We are all readers of The Power House to learn and benefit by the articles which appear therein.

Mr. Orr, in the December, 1909, issue, believed that the tension on the studs does increase. He brought before us another question, an offspring of the original, which I believe has not yet been discussed through these pages: "Does the pressure of the steam against the inside of a cylinder cover lessen the screwing-up pressure with which the studs hold the cover against the cylinder end?"

The Writer's Theory.

The accompanying sketch will, I hope, bring to the readers my theory of the above two questions, and for convenience of illustration, only two studs are dealt with, the ultimate total result being obtained by multiplication. In the figures a cover and section of cylinder are shown. Fig. 3 has the stud nuts (n) screwed up against the cover by hand, leaving no tension on the stud except the weight of the cover, which in this instance need not be considered.

If a weight or pressure of 1,000 lbs. per stud, or 2,000 lbs. for two studs, acts on the inside face of the cover, the portion (a) of the stud is under a tension of 1,000 lbs., but the portion (b) is under no tension. Now, remove the 2,000 lbs. weight or pressure and tighten the nuts (n), so that there is a tension of 1,000 lbs. on each stud between the nut and the cylinder end; then hang a weight of 1,000 lbs. on each stud, as shown in Fig. 2. Previous to the weight being applied, there was no tension at (b), but now there is 1,000 lbs. at both (a) and (b), which leaves the nut (n) free to move, also the cover.

Again, if the weights are removed from the eyes of the studs and placed on the cover, as in Fig. 1, there should be 4,000 lbs. tension on the two studs at (a), that is, 1,000 lbs. due to the pressure of each nut and 2,000 lbs. on the cover. This is more clearly shown in Fig. 4, for, while the tension on each stud at (b) is only 1,000 lbs., at (a) the tension is 1,000+half the weight on the cover, or 2,000 lbs. If the weight on the

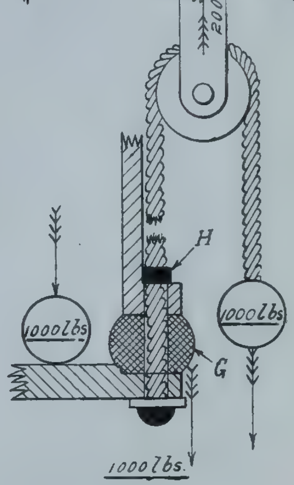

Fig. 8.

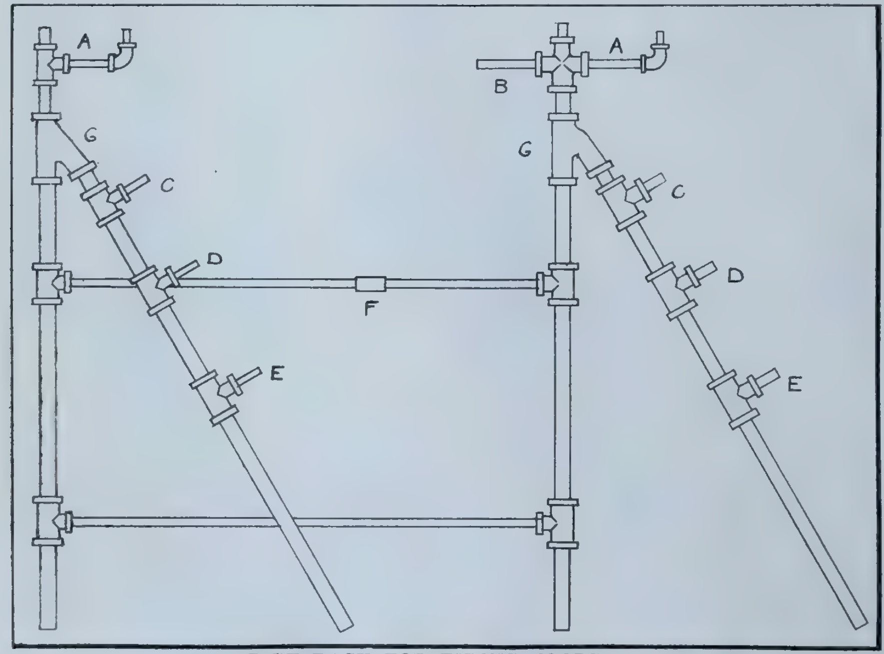
TENSION ON CYLINDER COVER STUDS—DIAGRAMMATIC REPRESENTATION.

cover were only 10 lbs., the portion (a) of each stud would have a tension of 1,000+half the weight on cover, or 1,005 lbs. In the above four illustrations the compression of the gasket and flanges are ont considered. Fig. 5 shows a simple pulley supporting two weights, so that while the pulley, bracket and pin are supporting 2,000 lbs., the rope is only under a tension of 1,000 lbs.

In Fig. 6, one of the weights is removed and the rope secured to a washer below the cylinder cover, the gasket (G), enlarged to show the action of compression and extension, being placed between the cover and the cylinder end. The gasket under compression exerts a pressure tending to force the cover away from the cylinder, but is prevented by the tension in the rope or bolt. Now, if a weight equal to the tension in the rope be placed upon the cover, as in Fig. 7, the pressure of the gasket due to compression would force the cover away from the cylinder until the gasket (G) was free, but the rope retains a tension of 1,000 lbs.

Suppose we only place a weight or pressure of 100 lbs. on the cover, the compression of the gasket will be reduced one-tenth, and the pressure due to compression will only be 900 lbs. If the rope, as in Fig. 8, be secured as at (H), while the gasket is in compression, and the rope cut, or replaced by a bolt, the gasket would still exert a force of 1,000 lbs. Now, place the weight or pressure on the cover, and the tension on the rope or bolt will be 2,000 lbs. If a weight of only 15 lbs. be placed on the cover, the tension will be 1,015 lbs. This is what I understand from Newton's Third Law of Motion:—"To every action there is always opposed an equal and contrary reaction."



PIPE RACK FOR FIRING TOOLS.

If the tension of the bolt exerts a force to keep the cover against the cylinder, then the compression of the cover, gasket and cylinder end exert a like force to separate the head and the nut of the bolt, or the nut and opposite end of the stud; therefore, any additional pressure on the cover from the inside must be counteracted by an equal force, and if the studs do not take this extra pressure, what does?

I am not positive that the foregoing reasoning is correct, and I hope that some readers will kindly describe and illustrate their theories, and have them published for the benefit of engineers at large, as the question seems to be of considerable interest to a wide circle of readers.

* * *

PIPE RACK FOR FIRING TOOLS.

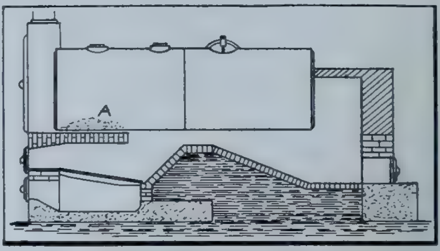
By J. E. N.

THERE have been some curious and wonderful arrangements made and used from old pipe fittings and scrap pipe. Here is another one, and which I am told is new. It is made from one inch pipe screwed tightly into the fittings shown, and is used to hold the rake, hoe and other firing tools on the spikes (C) (D) and (E). If the fireman is the lucky owner of an extra slice bar or other tool, he can place it ready for business in case one of his regular kit gets broken, on the arms shown at (A), and if he has an extra shovel he can hang it on bar (B). The coupling at (F) is right and left hand. If required the half Y fittings (G) can be replaced with full Y's, in which case the rack would probably be harder to upset, but it would occupy much more space then if built as shown.

PROTECTIVE ARCH.

By C. Fenwick.

THE accompanying drawing shows an improved setting for return tubular boilers. The arch over the fire serves the double purpose of improving combustion and preventing the burning of the boiler. In nearly every case, mud and loose scale will lodge as shown at (A) in the drawing, and where very dirty water is used the arch will be a great help.



PROTECTIVE ARCH.

* * *

CONCERNING BELT SPEEDS.

By W. E. Mason.

I WISH to secure such information as will allow me to solve some belt speed problems. We had a chain drive enclosed in a case and the chain ran in oil. The pulley diameters were 15 in. and 4½ in. respectively, but we could not get the speed required, namely 2,000 r.p.m.

The chain drive made more noise than anyone could believe, and after three weeks running, the chain snapped and the case was damaged beyond repair, one of the parts of the chain embedding itself 1½ inches in a brick wall, 30 ft. from the pulleys. We did away with the chain drive after that experience and installed belting with larger pulleys. The engine room is comparatively quiet now, although there is still room for improvement. I want to know the speed of the belt in feet per minute, and to get the rule for ascertaining belt speeds. Do you think the speed is too fast? If so, what will be the remedy. The belt is double cut square, laced, and 8 in. wide.

To intelligently answer the foregoing, the diameter of the belt pulleys should be given.—Ed.

Lining-up Single Cylinder Slide Valve Engine.—F. H., Montreal, writes.—As I am a subscriber to The Power House may I take the liberty to ask a question? Will you please tell me a short and effective method to line up a single cylinder slide valve engine, also, how to line up, with the crank shaft and flywheel in position.

ASSOCIATION AND PERSONAL

A Monthly Record of Current Association News and of Individuals Who Have Been More or Less Prominent in the Power Field.

LUNKENHEIMER CO. ANNUAL DANCE.

On Saturday evening, December 13th, possibly the largest attended dance ever given in Cincinnati took place at the Armory in that city. The event was the annual dance and entertainment given by the Lunkenheimer Company to its employees and their families, at which it is estimated about 5,000 were present. The Lunkenheimer Company is well known universally as large manufacturers of high grade engineering specialties their executive offices and factories being located in Cincinnati, Ohio, with branches in New York, Chicago, Boston and London.

The company prides itself upon the high quality of its products, but as the officers will explain, this high quality is due to a great extent to a like quality of the men employed and the harmony that exists among them. One of the principal objects of these annual entertainments is to aid in maintaining this harmony, and by bringing the employes together in a social way, meeting each other in a different light from that of business, a feeling of good friendship is created, such as could not be accomplished in any other manner. Again, the size of the Lunkenheimer plant is of such large proportions that the workmen of one department do not have an opportunity of often meeting those of another, but by congregating them in a manner which it has been the practice of the Company to do for many years past, they learn to know each other, so that when they do meet in the factory or any other place, they meet as friends and not as strangers.

The Armory at which the entertainment was given is the largest hall for purposes of this kind in Cincinnati. It was beautifully decorated with holly, and red, white and blue displays. A temporary stand was erected in the centre of the hall for the First Regiment Band, which furnished the music for the dancers, the band consisting of forty pieces and picked musicians. The lower floor of the building was fitted up as a rathskeller, where all kinds of refreshments were served gratis, and where a large orchestra was in attendance. On entering the building, the men were given a case of cigars, and the ladies and children were presented with souvenirs.

During the week of December 8th, all of the travelling salesmen representing the company assembled for a general conference, and they in a body also attended the affair. The look of general satisfaction depicted on the faces of all, when leaving, clearly showed that the efforts of the company for the welfare and happiness of the employes were highly appreciated.

MANITOBA ASSOCIATION OF STATIONARY ENGINEERS.

The Manitoba Association of Stationary Engineers is different from the other Associations throughout the Dominion, having been incorporated for the purpose of issuing certificates to steam engineers who wish to operate in the Province of Manitoba. The grades of certificates issued are first, second and third class. The third class allows the holder to take charge of and operate any steam plant up to 50 h.p., the second class up to 200 h.p., and the first class up to any h.p. These certificates are secured through examinations, which are held every three months in Winnipeg. A meeting of the members of the Association is held each year for the election of a Board of Directors. This consists of five engineers, who meet from time to time to pass upon applications and transact business. A permanent secretary looks after the clerical work, and takes up cases of parties operating without certificates in the Province.

The directors elected for the present year are F. R. Bonner, Ernest Prentice, Thos. Watson, James Reid, and E. Mehmel. F. R. Bonner is President of the Board. The secretary is H. R. Scrimes, 499 Main Street, Winnipeg, to whom all communications should be sent.

BRITISH COLUMBIA ASSOCIATION OF STATIONARY ENGINEERS.

VANCOUVER Lodge No. 1, British Columbia Association of Stationary Engineers, held its first annual dinner in the Granville Palace Hotel, Vancouver, on New Year's Eve, December 31, 1913. Some seventy-five guests, among whom were a fair sprinkling of ladies, partook of the excellent repast provided by "Mine Host"—Rollins Bros. A feature of the evening, and one which contributed largely to the general success of the function, was the absence of long speeches, the place of the latter being taken by songs, recitations, etc. Only four toasts were proposed and honored, these consisting of "Our King," "Canada," "The President of the United States," and "The Ladies." Mr. John Stone performed the duties of toastmaster with much acceptation.

GRAND LODGE CONVENTION, NORTH-WEST ASSOCIATION STATIONARY ENGINEERS.

THE Annual Convention of the Grand Lodge, North-West Association of Stationary Engineers, opened in the Frank Hotel, Frank, Alta., on Monday, December 29, 1913. The Grand Lodge opened at 10 a.m., with Grand Chief Stewart, of Edmonton, in charge, and Grand Secretary W. G. Singer, of Edmonton, and delegates from the different local lodges in attendance. The Grand Chief gave a very able address, covering the past year's work, and expressed pleasure at the condition in which he found the newly-organized Frank lodge. After laying out the programme of proceedings, the meeting adjourned at 1 p.m. for lunch, following which the Grand Officers and Delegates visited the different plants west of Frank at Blairmore, Coleman and McGillivray, and were shown around by the officials in charge. A night session was held at eight o'clock, and much important business was transacted.

On Tuesday, December 30, the delegates visited plants east of Frank, and met with similar courtesy from the officials at Belle Vue, Hillcrest, Maple Leaf, Passbuy, and Burmis as was accorded them on their visit to plants westward. The Convention was called to order at 3 p.m., and adjourned at 6.40 p.m. A mass meeting was held at 8 p.m., at which questions of interest to the Association were thoroughly discussed. A paper was read by Jas. Donelly, erecting engineer of the Hudson Bay Co. at Edmonton, on steam turbines, their design and operation.

On Wednesday, December 31, the Convention was called to order at 10 a.m., when all business was completed, and officers for the ensuing year elected as follows:—Grand Chief, J. D. Stewart, of Edmonton, re-elected; Grand Vice-Chief, S. D. Shearer, of Blairmore; Grand Sec.-Treas., W. G. Singer, Edmonton; Grand Organizers, W. Simpson, Frank; Jos. B. Verdon, Edmonton; Grand Door Guard, C. Sherratt, Coleman. The Grand Chief upon his re-election was presented with a handsome memento by the delegates. The Convention closed at 6 p.m., December 31, 1913.

On New Year's Eve a banquet was held in the Frank Hotel, and served as a fitting climax to the Convention. At 9.30 some fifty guests partook of a sumptuous repast, served in excellent manner, and made more pleasing by the tasteful and seasonable decorations. The taking of a flashlight picture of those assembled was an acceptable feature at this juncture, following which a lengthy programme was proceeded with. Rev. W. T. Young acted as toastmaster. The opening number was a violin selection by C. and P. Slopak, two Bohemian boys, only a few months out from the Old Land. Their efforts were such as to merit repeated encore demands.

The toast of the Grand Lodge was replied to by Grand Chief Stewart, who remarked that, while all previous Conventions had been held in cities, Frank had the honor of the largest and best gathering in the history of the Provincial organization. He spoke on the object of the lodge as being mainly educational on behalf of its members. They did not believe in the attitude of many to-day, who said to their employers, "You must give us higher wages," but rather by a spirit of co-operation and better equipped men to merit the higher wages. A piano solo by Mrs. W. T. Young followed this toast.

J. Delaney, of Belle Vue, replied to the toast of the Frank Lodge. He spoke of the youth of the lodge, also what it stood for, as well as what it meant to its members, and illustrated the need of unity among men by a story of how the guards of an asylum are never afraid of more than one man at a time, because lunatics never combine. After a well-rendered recitation by H. Ryan, entitled "The Road to Heaven," the toast to Edmonton Lodge was done full justice to by W. G. Singer. The next item on the programme was the toast to the Frank Hotel. W. Simpson replied to the toast, and, in doing so, referred to the geniality of the proprietor, W. A. Manuel, to his kindness to the lodge, and, in spite of the many ups and downs which the town had experienced, to his having stuck to it faithfully.

John Delaney recited "The Cremation of Sam McGee," after which J. Scott, of Coleman, replied to the toast of the "Master Mechanics" in one of the most practical speeches of the evening. He congratulated the lodge on its aims, and assured them that as long as it helped its members to be better men it would be a success. To be a successful engineer it was necessary to be a sober, well-controlled men, these being as important from an educational standpoint as writing examinations. A violin selection from the Slopak boys and a recitation from H. Ryan, entitled, "Trouble in Amen Corner," followed. The toast of the ladies was responded to by the chairman, and, needless to say, full justice was done.

The meeting closed by the singing of "God Save the King," after which the company dispersed.

READERS' QUERIES.

Feeding Boiler Compound.—D. H. P., Winnipeg, Man., writes as follows:—At the plant of wihch I have charge, we are going to instal a Detroit trap, and the question arises how can I get my boiler compound into the trap without using a feed pump? This latter I am going to cut out altogether, except as a standby. The compound I use contains too much sediment, so that I could not very well use a lubricator.

* * *

Replacing Gauge Glasses.—One of our subscribers in Guelph, Ont., has experienced trouble through gauge glasses breaking within a few hours of their replacement after removal and cleaning. He says no such trouble arises when putting in new glasses, and believes, therefore, that an explanation of the breakage on replacement is possible, which, if put to practical use would eliminate the latter. Will some of our readers give their experiences in this feature of boiler room engineering?

* * *

Subscriber, Norwood, Man., wishes to have a description of the principle on which a reducing valve operates, and to have a sketch illustrative of the constructional features. He also sends the accompanying sketch, illustrative of a steam pipe line (A.A.) with branch pipe (B), and would like to have an expression of opinion as to which is the correct arrangement.

TEACHING AUTOGENOUS WELDING.

AUTOGENOUS welding, which only a few years ago was looked upon as a novelty of somewhat doubtful value, has now become an almost indispensable adjunct to many industries . The oxy-acetylene and oxy-hydrogen torch, both for welding and cutting, is now recognized as a very great labor-saving device, and is becoming widely used in the metal-working trades, not only for repair work, but also for manufacturing purposes.

In autogenous welding, it is universally admitted that the reliability of the results attained are very largely dependent on the skill of the operator, and this will probably always be the case. In small plants, where the process is only occasionally employed to effect repairs to some badly needed forging or casting, it has been usual to call in an expert employed by some firm making a specialty of this class of work, and even in our large railway shops, where the process may be in practically continuous use, it is not uncommon to find only one or two men, among the many hundreds employed, who know anything about it.

This has perhaps been unavoidable hitherto, as most of the operators have picked up their welding knowledge in the shop where they were employed, and while these have for the most part become experts, when they leave the shop or are promoted to some higher position, it is hard to replace them, an inexperienced man having usually to be broken in "ab initio" to fill the vacancy. It is, therefore, interesting to note that the Montreal Technical School, recognizing the local demand for skilled welders, are conducting a weekly evening class in autogenous welding at which practical and theoretical instruction in the art is being given by experts. Each lesson lasts two hours, and there are ten lessons in the course.

While it is not suggested that a student can become an expert welder after only twenty hours' instruction, much can be done in that time to impart a good grounding in the subject, and to stimulate a desire for further knowledge of the work. Several men who are employed at this work during the day are attending the class, which is an extremely encouraging sign, for it were safe to say that the majority of operators are not familiar with the theoretical side of the subject, though they may be able to obtain very fair results in practice.

The present is the second winter that this course has been conducted. Last year it met with great success, and many old students are now taking a second-year course. This move on the part of the management of the Montreal Technical School is to be heartily commended, and we wish the class continued success. It is hoped in the near future to give instruction in this subject to day students also, the difficulty hitherto having been to secure the services of practical demonstrators during the day time.

Autogenous welding, in addition to filling an important niche in mechanical engineering work generally, becomes, in the case of power plant operation, of inestimable value in preventing shut-downs of long duration. Expensive repairs to broken or fractured parts of the equipment, and even the necessity being obviated of replacement by entirely new pieces, have been and are being offset by the successful application of the process. It is incumbent, therefore, that men in charge of power plants, and particularly those directly responsible for advice concerning the carrying out of repairs, should be conversant with what is being accomplished in the direction of saving valuable equipment, which disaster may have overtaken, and of being able to discern when it is possible to have the work done, to all intents and purposes without removal from the plant. The progress of autogenous welding has been marked by rapidity and success due to merit, and it is our belief that near future development will increase its value even more so than in the past.

REFRIGERATION DEPARTMENT

MULTIPLE EFFECT ABSORPTION MACHINES.—I.*

By Edmund Altenkirch, Berlin.

ABSORPTION machines play, at the present time, a far more important part in the United States of America than in any other country, and new developments in this type of machine will consequently there obtain earliest recognition as to their scope.

In a paper published early in 1913 in the "Zeitschrift f. d. ges. Kalteindustrie," I have shown that the absorption machine, in regard to the cooling water heat flow, enjoys a great advantage as compared with the steam engine, and compression refrigerating machine; it being capable of following in an ideal manner, the changes of temperature in the heat imparting and absorbing media. This approximation to the Lorenz cycle is practically, in itself, nothing new. It is merely a recognition of a fact which we might have realized long ago; that the absorption machine, subject to certain essential exterior conditions, is more perfect than other thermo-dynamic machines.

Disregarding the processes within the machine itself, machines that operate by means of the vapor of pure fluids, require taking into account two extremal factors, cooling water and heat flow, in order to be generally reversible; namely, exceedingly large heat transmission surfaces and—provided latent heat does not come into play—unlimited large quantities of heat carried. Machines, however, which operate by means of vapor mixtures of binary and higher fluid mixtures, require for theoretical perfection only infinitely large surfaces for the flow of heat. The second condition disappears or is at least restricted. It is only carriers of limited quantities of heat that are capable of attaining the best approximation to the reversibility of the total process.

This advantage of the absorption machine in decreasing the temperature difference between the surroundings and the machine would practically in many cases permit an improvement in the utilization of the heat, if, on the other hand, it were not for the disadvantage that the temperature differences, and, with this, the irreversible heat losses within the machine, were not of themselves, so much greater. The latter, however, appeared until recently to remain theoretically and practically quite unavoidable and entirely beyond doubt.

I could show how, by returning the rich solution in counter-current through the absorber as well as by returning the weak solution in counter-current through the evaporator, the temperature differences within the machine itself could be reduced almost at will. The supply of heat to the evaporator, the emission of heat from the absorber, are by this means equally diminished. With stronger outflow of gas, the heat exchanger is eliminated, and by overheating with even more active flow of gas, it is also possible to furnish more cold than the quantity of heat supplied to the evaporator.

These improvements would, however, be incomplete if they were not supplemented in another direction. They apply so far, only to the driving engine of the absorption refrigeration machine, and to the absorption machine in a restricted sense. For this, however, the Lorenz cycle appears less important, when we consider that the evaporator is more usually heated by steam. The supply of heat is effected therefore mainly at a definite temperature point. Of course, the supply of heat may be effected in another way, but even then, the Lorenz cycle does not come fully into play, because the condenser is still always confined to a fixed temperature. The quantity of cooling water required is thereby predetermined in many cases, and a saving in the absorber amounts on the whole to very little.

Taking Full Advantage of Lorenz Cycle.

In order therefore to make full use of the great advantage of the Lorenz cycle in the condenser and evaporator as well, the pure fluid is to be replaced by a binary mixture. This was accomplished about twenty years ago by the German inventor Osenbruck. He allowed the absorption machine to work in the reverse direction and it only remained to apply to the machine working in this reverse direction the principal counter-current circulation of the solutions, so as to make the temperature differences within this machine as small as desired. I have more closely described this reversed absorption machine which can also be operated by a compressor and which consequently indicates an improvement of the compression machine, in the "Zeitschrift f. d. ges. Kalteindustrie," and the better to distinguish it have given it the name of "resorption machine." The condenser, therefore, becomes an absorber, to distinguish it from the absorber of the driving engine, but I have named it "resorber," while the evaporator becomes a generator which might be named a "distiller."

With the help of these improvements, the former theoretical inferiority of the absorption machine is changed to the opposite degree, and the new absorption refrigeration machine leaves as regards reversibility nothing to be desired. It possesses, in addition, the unequaled faculty of adaptation to the above described requirements of practice that the compression machine does not possess, and the advantages cannot fail to extend the field of usefulness of the absorption machine. A contribution to the theory of these machines shows, however, that it is not so easy, even with the overheating to raise the heat ratio of the absorption machine to two or three times what it was, in order to equal the economy of the compression machine driven by a steam engine, the thermo-dynamic reason for this being that by increasing the final temperature of the distiller, the average temperature of the absorber becomes correspondingly high. I will therefore indicate an entirely different method which, without making use of the increased temperatures, enables us, with the absorption machine, even as an exhaust-steam machine or at least as a back-pressure exhaust-steam machine, to furnish just as much cold for the volume of steam supplied as a good compression machine even when driven by a good steam engine.

Multi-Stage Absorption Machine.

This is effected by the multi-stage absorption machine, in which the absorption is effected in several stages. This was first described by the English engineers Cracknell and Stokes, in British letters patent 16,335, 1908. The weak solution gives off more gas in a second volatilizer, under lower pressure, before going to the absorber. The gas thus obtained is used in the second absorber, for the further enrichment of the solution coming from the first absorber. The pressure in the second absorber is higher than that in the first and corresponds to the pressure in the second volatilizer. This machine supplies a well dried vapor and is capable, even with warm cooling water, of working well, but consumes, for one kg. of usefully volatilized ammonia, on the whole more heat of volatilization and more refrigeration-calories than a simple machine, because the ammonia volume, expelled from the volatilizer by additional heat is again absorbed in the second absorber, without producing any cold.

---

*From a paper read before the Second Section of the Third International Congress of Refrigeration, Chicago, in September last.

Another multi-stage absorption machine is that of Gardner T. Voorhees. The ammonia liquefied in the condenser in this machine passes first into a preliminary vaporizer. Here, at medium pressure and not very low temperatures, partial evaporation and cold production takes place, which serves for the preliminary cooling of the liquefied ammonia and of the water of condensation for the distilled-water ice making. The remainder of the ammonia passes into the principal evaporator. The gas developed in the preliminary evaporator is absorbed in an auxiliary absorber, under suitable pressure by the solution enriched in the main absorber and forced by a pump into the auxiliary absorber. The solution thus enriched passes into the volatilizer.

This machine, likewise in consequence of the higher initial concentration in the volatilizer, furnishes a drier vapor, and consequently requires comparatively somewhat less heat of volatilization and less refrigeration-calories. If we include in the useful refrigeration, the cold produced in the preliminary evaporation, which serves to cool the hot condensed water or enhance the useful refrigeration output—a question concerning which, however, a good deal might be said—the heat conditions are more favorable. It does not, however, go beyond a maximum which materially exceeds that of other good absorption machines working under favorable conditions, for the vapor produced in the evaporator by a given expenditure of heat, can, with a single evaporation, furnish no more cold than corresponds to its heat of evaporation.

The multiple effect absorption machines of Cracknell and Stokes and Gardner T. Voorhees, consequently hardly embody any progress in regard to utilization of heat. This may, however, be attained by the application to the machines in question of our system, in other words, by counter-current circulation and over-lapping of the temperatures. The over-lapping of temperatures, will be facilitated in both machines by the lower initial temperature of the volatilizer and in the Cracknell and Stokes machine by the high initial temperature of the absorber. Nevertheless, the object indicated above, a cold output greater than the supply of heat, is impossible or at best difficult of attainment by this means. The multi-stage absorption machine, such as has been worked out by me and my collaborator Tenckhoff will now be more closely described.

The multi-stage absorption machine of our system makes use of the already mentioned resorption machine. The vapor which leaves the evaporator does not pass directly into the absorber, but is first passed through such an independent resorption machine. The vapor is consequently reabsorbed in a resorber and again vaporized in a distiller. The ammonia produced in the volatilizer of the absorption machine consequently passes through two refrigerating machines, one behind the other; producing cold twice. Where a further resorption machine is introduced, three times, etc., the heat ratio can therefore be raised to an unlimited extent, if only the temperature differences in cold production are small enough to permit of several stages.

STAFF OF STEAM BOILER BRANCH, DEPT. PUBLIC WORKS, PROVINCE OF ONTARIO. READING FROM LEFT TO RIGHT:
D. M. Medcalf, Chief Inspector.
G. Guillet, Clerk and Bookkeeper. W. H. Bradt, Inspector. T. J. Main Inspector.
G. Drummond, Inspector. A. Brown, Inspector. W. Burns, Inspector.

Multi-Stage Absorption Machine Operation.

The rich solution in the absorber is driven by means of the pump into the volatilizer. Here, with the aid of a supply of heat and rising temperature, it is distilled. The weak solution leaves the volatilizer, and by means of a regulating valve, returns to the absorber, where, under heat abstraction and sinking temperature, it absorbs gas. The absorption machine driving parts need not differ from those of other absorption machines.

The gas developed in the volatilizer passes through a gas-drier into the condenser, is there liquefied, and, through the regulating valve, reaches the evaporator. This part of the machine is likewise unchanged. If the gas were to proceed directly into the absorber, the old machine would be complete, but instead, the gas passes into a resorber, and is there taken up by a relatively weak solution, which with loss of heat and reduced temperature, enriches itself. The rich solution thus obtained, passes a regulating valve, and enters the distiller. Here, yielding cold, consequently with increased heat and rising temperature, it dries off the gas again. The degased solution is forced by a pump back into the resorber to again absorb gas, and the gas that has been set free in the distiller passes finally into the absorber and begins the circle anew.

◆

Question.—A water tube boiler has 150 tubes 3¼ inches outside diameter by 15 feet long. What is the heating surface in the tubes.

Answer.—First calculate the circumference of a tube 3¼ inches outside diameter and divide the result by 12 in order to get the answer in feet. Multiply this result by 15 feet length, and we shall get the heating surface of one tube expressed in square feet. The total heating surface of the tubes will be 150 times this amount.

Thus $$\frac{3.1416\times3.25\times15\times150}{12} = 1914.41$$

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

A "BENNIS" COKING STOKER INSTALLATIONS.

THE accompanying description and illustrations refer to an installation of what is known as the "Bennis" high temperature, smokeless and gritless machine coking stoker at the London Paper Mills, Dartford, England. Coal is transported by means of Bennis U-link chain conveyors, feeding distributing shoots through openings in the bunkers. The plant consists of:

1.—A receiving hopper with supports placed outside the boiler-house on the bank of the river, in such a position that the cial can be deposited into the hopper by a crane and grab.

2.—An overhead coal storage bunker having a capacity of about 330 tons of coal.

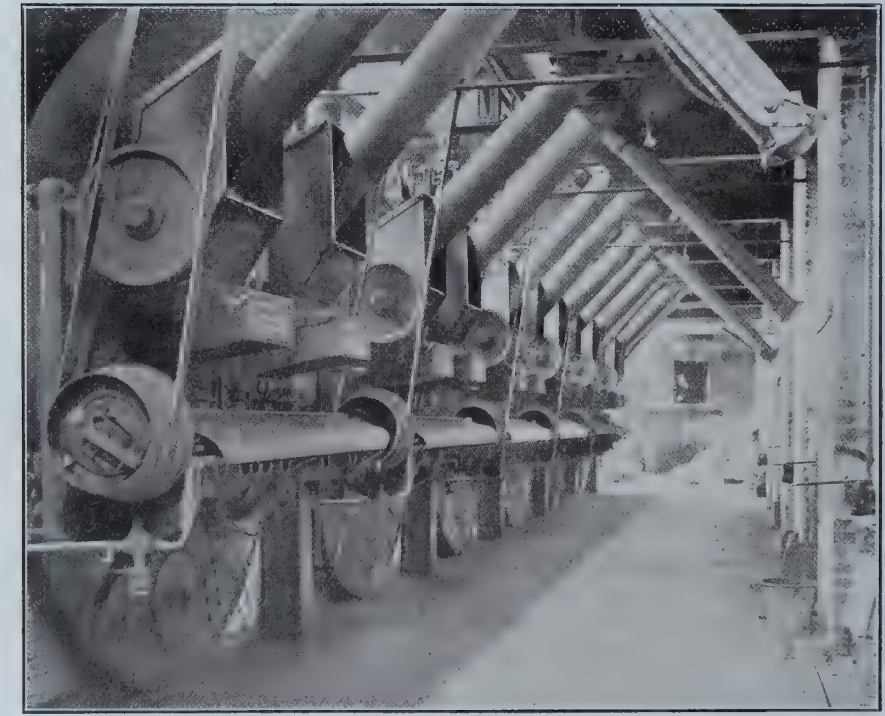

Fig. 1—A range of "Bennis" High Temperature Machine Coking Stokers keeping steam in the Boiler-house of the London Paper Mills.

3.—Bennis U-link chain conveyors with driving gear, shoots and all supports.

4.—Shoots to carry the fuel from the bunkers to the hoppers of the stokers by which the boilers are fired.

The method of operating the plant is as follows:—The coal is brought up to the wharf in barges. A grab load of coal is raised from the barge by the crane, and dumped into the receiving hopper from which it flows through an outlet into the chain conveyor, which is placed immediately beneath. The first portion of this chain conveyor is carried up an incline and the coal is thus raised to the level of the top of the bunkers. The conveyor then passes horizontally over the top of the bunkers, and the coal is dropped through openings into the storage bunkers beneath. The coal flows by gravity from the storage bunkers into the storage hopper, and a valve is placed at the end of each shoot to control the supply of coal.

The conveyor is of the well-known Bennis U-link chain type of which this firm has made a specialty during the last twenty years. It has a capacity of 40 tons per hour, and is driven through suitable reduction gear by a separate motor. The overhead coal storage bunkers are built over the firing floor; they are about 80 ft. long by 11 ft. wide, and have a total capacity of about 330 tons. The boiler-house wall is utilized for one side of the bunkers, while the other side consists of a reinforced brickwork wall. The bottoms of the bunkers are hoppered in shape, and are formed out of rolled steel plates with suitable stiffeners and connections.

A number of rolled steel joists run the whole length of the bunker to form supports and carry the weight between the stanchions. These longitudinal joists are supported in their turn by other transverse joists spanning the firing floor and carried at one end on substantial stanchions, resting on the floor; the other end being built into the wall of the boiler-house. These stanchions are also used for supporting one side of the main boiler-house roof, and a light roof is built over the top of the bunkers themselves. Access is given to the conveyor chamber over the bunkers by ladders and gangways, arranged so that all running parts are easy of access for inspection and lubrication. The bunker was designed to take full advantage of the existing buildings and to give the required storage without forming any obstruction to the movements of the boiler attendant. It is so arranged that future extensions can be easily affected.

The work of the U-link chain conveyors, as already stated, is to feed the coal to the bunkers which deliver it by means of openings into the distributing shoots which in turn deposit it in the stokers. The illustration, Fig. 1, affords a good view of this range of stokers with the shoots in position and in close connection with the bunkers immediately above.

It is of course essential that steam-raising in paper mills should be absolutely smokeless and gritless, because of the immense harm that can be done to both paper and pulp in various stages of manufacture should grits and smuts be emitted from the chimney and so find their way into the incomplete manufactures.

The Bennis coking stoker for paper and pulp mills has been referred to more than once in these pages, it is, therefore, sufficient here to point to the fact that the installation described was a development due to a satisfactory experience

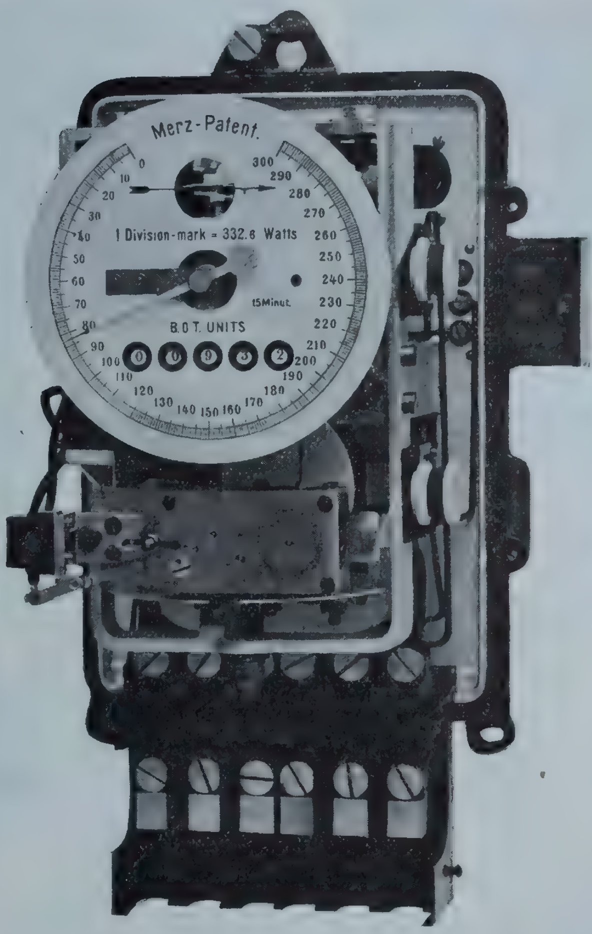
What the Meter does

1. Gives the kilowatt hours.
2. The highest load demanded in watts on a time average of say 15, 30 or 60 minutes.

The accurate measurement of these two quantities enables a true load factor system of charging to be adopted.

What can be done with the Meter

1. Charge an annual sum per K.W. year or Horse power year to cover capital and standing costs.
2. Charge a low straight rate per K.W. hour based on running costs and profit required.



SIEMENS LOAD FACTOR METER

with a similar installation at another of the Paper Co.'s mills.

The following are among a number of the advantages claimed for the Bennis coking stoker.

(1)—The power of rapidly lighting back which carries with it the power of feeding a much larger amount of fuel on to the furnace and getting it burnt.

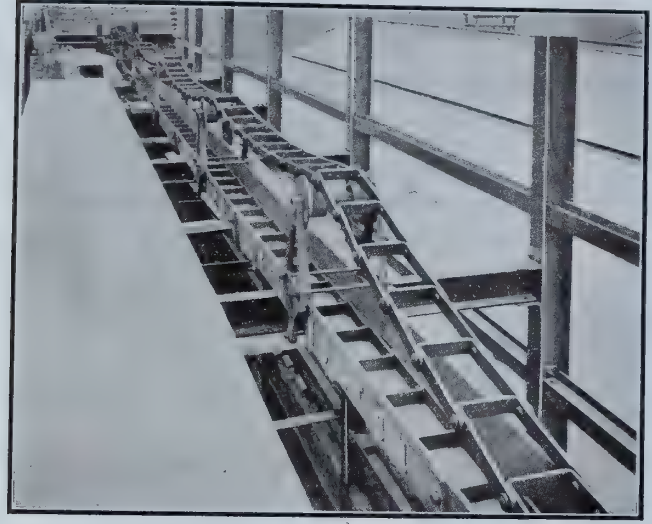

Fig. 2—"Bennis" U-link Chain Conveyor which in part of its travel is inclined to carry the coal to the level of the top of the bunkers. It deposits its contents by means of openings into the storage bunkers beneath. It forms part of the "Bennis" installation of coal handling plant in the boiler-house of the London Paper Mills.

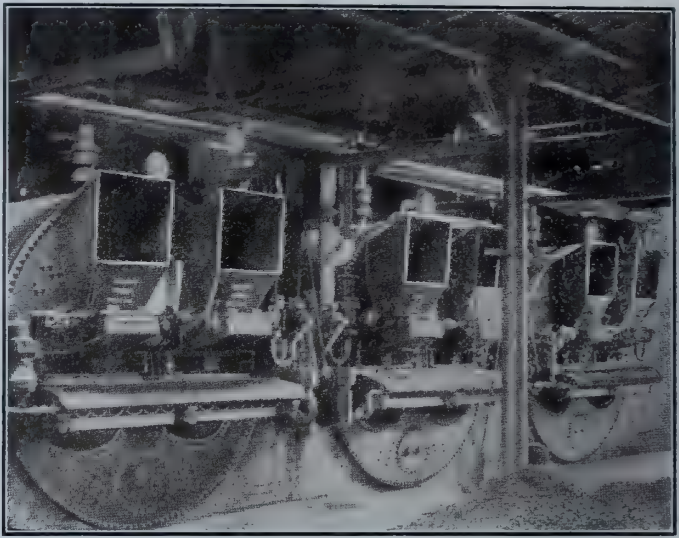

Fig. 3—This range of "Bennis" Smokeless and Gritless Coking Stokers is in operation at the A. E. Reed & Co. Farncombe Paper Mills.

(2)—A higher and more even furnace temperature than has hitherto been possible with coking stokers. This is induced by the scrubbing of the coke by the air blown into the fire through the very fine air spaces of the compressed air furnace bars.

"CHURTON" MOTOR.

(3)—Maximum flexibility attained by the power of controlling the air supply to the compressed air furnace bars and the adjustment of the damper of the boiler; a combination adequate to control the rate of combustion.

(4)—Combustion without smoke, grits or dust; the compressed air furnace cleaning into the ash-pit, which is a closed chamber.

(5)—Simple and easy manipulation, there being but two adjustments for the fireman to make, one which determines the rate of feed by turning a nut, and the other which regulates the air-feed by means of a valve.

(6)—Low cost of upkeep, the bars being few and the feed motion simple.

(7)—Stoking bars which keep the fire at a nicely-calculated distance from the boiler front, thereby obviating the hitherto unavoidable injury done to the whole furnace front by parts becoming red-hot.

(8)—Air-cooled fire-doors which prevent damage either to stoker or boiler.

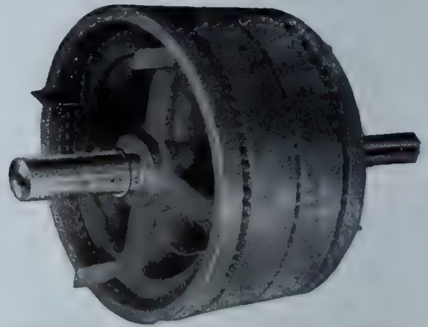
George H. Tod, Manning Chambers, Toronto, is the Canadian representative of the manufacturers, Edward Bennis & Co., Bolton, England.

◆

THE "CHURTON" INDUCTION MOTOR.

THE accompanying illustrations show a high grade induction motor as manufactured by the T. Harding Churton Co., of Leeds, England, who are specialists in producing alternating current motors. By giving unremitting attention to this particular line, they claim to have reached as near the acme of perfection as possible.

Noteworthy among the details of construction of Churton motors may be mentioned the connecting rings of the short current rotor. The usual methods of connecting these rings to the rotor conductors by bolts and nuts, or by riveting, are not infrequently causes of trouble due to the effects of continual expansion and contraction, and the efficiency of a motor with the rotor so constructed may seriously depreciate after working for some time. Another method of connecting the conductors by wires interlaced around the ends and soldered together has the disadvantage that the solder is apt to be melted off by temporary heavy overloads that the motor should sustain without injury. To overcome these difficulties the Churton people introduced their "cast welded" system, in which the connecting rings are, by a special process, welded direct to the conductors, thus obviating joints of any kind. This method has proven entirely successful, the rotors so constructed being practically indestructible.



"CHURTON" SHORT CIRCUIT ROTOR.

The Stuart Machinery Co., Ltd., of Winnipeg, Man., are the Western Agents for "Churton" motors, and carry a stock of sizes ranging from 1 to 50 h.p.

◆

Arthur Grace, recently elected Commissioner of Public Works, Lethbridge, Alta., went there as engineer in charge of the construction of the Alberta Railway & Irrigation Co.'s irrigation works. He has had lengthy experience as an engineer in railway construction, and has had considerable civic experience in the construction of waterworks. He is an authority on gravity systems.

Good Reasons

why
you should use

D. K. McLAREN'S

Genuine British Oak-Tanned

Leather Belting

Only the best centres of carefully selected hides are used, and these are tanned by the slow, old-fashioned British Oak method which assures maximum strength and durability.

It has a grip that means less slip—hence the transmission of more power.

It is thoroughly stretched before being placed on the market, assuring but little attention when in service.

May we have the opportunity of furnishing you with references and full particulars?

Genuine Oak

POWER PLANT DEVELOPMENTS

A record of current municipal, manufacturing and general industrial projects, involving steam, gas, oil, electricity, air and water power equipment requirements.

Electrical

Neepawa, Sask.—The ratepayers recently voted $18,000 for the erection of an electric power plant.

Winnipeg, Man.—The Kildonan council have applied to the city of Winnipeg for the lighting of Main St., from the limits of the city to the municipality.

Ottawa, Ont.—The Minister of Railways has approved the plan of the Cedar Rapids Power Company for its proposed transmission line from the Rapids to Cornwall.

Toronto, Ont.—Among the municipalities which voted for Hydro-Electric power this week were, Wallaceburg, Hanover, Fergus, Elora, Strathroy, Tilbury and Chatham.

Hamilton, Ont. — W. C. Hawkins, managing director of the Dominion Power and Transmission Co., believes construction work on the new steam power plant will commence in March.

Paisley, Ont.—The new council will deal with the extension of the waterworks, and the electric lighting system will be discussed, as the power is not equal to the number of lights being used

Sydney, N.S.—The Broughton Coal & Iron Co., Broughton, N.S., are considering an electric plant capable of taking care of 2,000 tons of coal per day, the central power plant to be located at Broughton.

St. Catharines, Ont.—The Niagara, St. Catharines and Toronto Railway is erecting a power house on Welland Ave., 40 x 35 feet, costing $45,000. The Canadian General Electric Co. is supplying the equipment.

Yarmouth, N.S.—The special committee recommends that a contract be given to the Northern Electric & Mfg. Co., of Montreal, for apparatus, etc., for a 3 circuit system, compressed air plant, 60 cycle, 3-phase, 220 volt circuit air compressors, motors, etc., at $2,000; battery switchboard, etc., at $1,587; wire, labor, etc., at $425.

London, Ont.—The remaining equipment necessary for the furnishing of hydro power to operate the street railway system has been shipped from Montreal, and will be completely installed by the end of February. The Company is using only part hydro at the present time, but after March 1 will be using it exclusively.

Quebec, Que.—The Provincial Waterways Commission, of which the Hon. S. N. Parent is president, has completed its report. It is understood that the Commission favors the harnessing of the St. Maurice River in the vicinity of Le Tuque by the building of a dam, which will make possible the development of 500,000 horse-power for industrial purposes.

Hamilton, Ont.—The Dominion Power & Transmission Co. have prepared plans for their steam auxiliary plant, which will occupy 14 acres east of the National Steel Car Co. plant. The main building will be 380 x 170 ft. by 50 ft. high. The transformer house will be 75x250 ft. Two units will be installed this fall, of 13,400 h.p. capacity. A unit will be added each year until the capacity is 88,000 h.p. W. C. Hawkins, managing director.

Municipal

Galt, Ont.—The city will spend $15,000 on its waterworks.

Woodstock, Ont. — Embro village wants Hydro-Electric power.

Guelph, Ont.—The city will spend $17,000 on two new street cars and a new feed wire.

Brantford, Ont.—Preparations are being made to connect the gas pipes with the old purification plant.

Hamilton, Ont.—A by-law providing $335,000 for extensions to the Hydro-Electric system was passed on Jan. 1.

Nelson, B.C.—The ratepayers have voted in favor of purchasing the street railway. The city recently took over the gas works.

Toronto, Ont.—The ratepayers on January 1 voted in favor of the city acquiring a portion of Toronto and York Railway.

London, Ont.—The by-law to loan $25,000 to the Grobb Mfg. Co., who will take over the London Foundry, did not pass at the municipal election on Jan. 1.

St. Vital, Man.—Third readings have been given two by-laws to provide $200,000 for water and sewer extensions, and to provide $35,000 for the new fire hall.

Athabasca Landing, Alta.—On Jan. 12 the ratepayers voted on a by-law providing $85,000 for completing and extending the present waterworks system.

London, Ont.—The Greene-Swift Co. have been given a franchise to lay steam pipes across Carling Street to heat the north half of Dundas Street, from Talbot to Richmond.

Davidson, Sask.—The ratepayers have voted in favor of spending $8,500 on an electric light plant, which is to be purchased from the Canada Gas Producer Co., Barrie, Ont.

Chatham, Ont.—The city is contemplating giving $410,000 for the Chatham Gas Co.'s gas and electric plants. It will be necessary to spend $50,000 to make the electric plant serviceable for the distribution of Niagara power.

Berlin, Ont.—Four rural districts of North Waterloo are preparing to take Hydro power. Their names and rates for 50 h.p. are as follows:—St. Jacob's, $29.08; Conestogo, $36.59; St. Clement's, $42.68; Floradale, 40 horse-power, $51.57.

Montreal, Que.— Controller Godfrey will recommend the building of a pumping station on the banks of the Lachine Canal opposite the present pumping station at Point St. Charles, with three pumps, costing $70,000, and to be finished in three weeks. This would be used only in case of an accident to the conduit.

Cyclone Cleaner with "Norivet" freely swinging arm head.

Clean Boilers Increase Profits

When your boilers are coated with scale, you are burning up money, which a LIBERTY CLEANER would save. A light coating of scale may mean a waste of 10%, and a ½-inch of scale a 50% loss of fuel.

Are You Sure Your Boilers Are Clean?

If you are not, it will pay you to investigate, and you should make your investigation THOROUGH. While the tubes in front may show little indication of scale, the centre may be heavily coated. A Liberty Cleaner will find the scale, and if you are in doubt as to their condition, let us send you one with which to make an investigation. If the tubes are clean, you don't need a Cleaner, and it can be returned to us without any expense to you.

Send postal for Catalogue.

Williams & Wilson, Ltd., Montreal. A. R. Williams Machinery Co., Toronto and Winnipeg.

"TWINS" EXCITE ADMIRATION

Because They Earn It

Think of a TWIN when you hear the word STRAINER

The installation of a Twin Strainer on your water supply line eliminates troubles, worry, waste of time and expense—because

It has two straining baskets—that may be cleaned alternately, thus permitting continuous operation.

It has but two valves—they are of the gate type and are always tight.

It gives a direct flow with minimum friction loss, insuring easy operation with no waste of energy.

In fact, a Twin Strainer is an insurance policy in active service.

Designed to protect and built to last.

Write for our bulletin.

THE TWIN STRAINER.

ELLIOTT COMPANY

6902 Susquehanna Street, PITTSBURGH, PA.

Manufacturers of Filters and Grease Extractors, Separators, Blow-off Valves, Feed Water Heaters and General Power Accessories.

CANADIAN REPRESENTATIVES:

Willams & Wilson, Ltd., Montreal. A. R. Williams Machinery Co., Ltd., Toronto and Winnipeg.

Refrigeration

Vancouver, B.C. — The Vancouver-Prince Rupert Meat Co., 125 Hastings St. W., will erect a cold storage warehouse.

Victoria, B.C.— The Swift Canadian Co. have completed a new $200,000 branch here. The refrigerating machinery, of 35 tons capacity, was installed by Huetteman & Cramer, Detroit.

Contracts Awarded

Winnipeg, Man.—The Board of Control will instal a duplex steam booster pump at the new King George hospital, and have awarded the contract to Cotter Bros. for $550.

Winnipeg, Man.—A contract has been awarded by the city to the Dominion Equipment Supply Co., representing the Dean Steam Pump Co., of Holyoke, Mass., for the supply of two new deep well pumps, with a guaranteed capacity of 600,000 gallons per day, costing $7,200 each, and guaranteed to be in operation by April 1.

New Incorporations

The Star & Hydro-Electric Co., Ltd., has been incorporated with a capital of $399,000, with head office at Montreal, to carry on business as electricians and manufacturers.

The Hilton Electric Co., Ltd., incorporated at Ottawa, capital $50,000, to carry on the business of electric engineers and contractors, and as dealers in and manufacturers of machinery, tools, etc., at Montreal, Que. Incorporators: Wallace R. Hilton, Aaron Issenman, etc., Montreal.

Trade Gossip

Winnipeg is considering the appointment of an assistant to City Engineer Ruttan to succeed the late R. D. Wilson.

Toronto, Ont.—The Toronto Waterworks Committee have just placed an order for two large pumping units. One unit consists of a 7½-million gallon Canadian Allis-Chalmers turbine pump, direct coupled to a Belliss & Morcom 580-600 h.p. triple expansion engine running at 300 r.p.m. The other unit is a 20-million gallon Canada Foundry turbine pump driven by a Belliss & Morcom 560-580 triple expansion engine running at 250 r.p.m. Both engines will run condensing.

Swedish General Electric Ltd.—The business heretofore carried in under the name of Kilmer, Pullen & Burnham, Ltd., will be continued by the Swedish General Electric, Ltd. The change of name has been adopted on account of its expressing better the class of business being conducted. Frank Pullen is president, the head office is in the Kent Building, Toronto, and branch offices are established at Montreal. Calgary and Vancouver. Swedish generators, motors and electrical equipment of all kinds are the firm's specialties, over 100,000 h.p., of these being already installed in Canada.

The Canadian Ingersoll-Rand Co. held their annual gathering of salesmen and officers at Sherbrooke last week. Those attending were:—E. W. Gilman, Montreal, general manager; N. M. Campbell, Montreal; J. W. Bell, Vancouver, B.C.; S. A. Williams, Lethbridge, Alta.; Wm. Carter, Winnipeg; G. R. Southee, Cobalt, Ont.; C. C. Hoyt, A. A. Bowman, B. H. Lyons, Toronto; S. W. Dugan, E. S. Winslow, J. McGuire, J. W. Davis, E. A. Lunderville, Montreal; J. P. Cotter, Sydney, C.B. Conferences were held every day, and on New Year's Day, the proceedings terminated with a dinner to the staff.

The Smart-Turner Machine Co., Hamilton, Ont., have recently secured the following orders:—The Armstead-Wolvin Co., Port Arthur, Ont., automatic feed pump and receiver equipment; the Black Donald Graphite Co., Calabogie, Ont., one force pump; the Corporation of Forest, Forest, Ont., duplex pump; Armstrong, Whitworth of Canada, Ltd., Longueuil, Que., one duplex pump; the General Hospital, Brantford, Ont., automatic feed pump and receiver equipment; Davidson & Smith Elevator Co., Port Arthur, Ont., automatic feed pump and receiver; Harbor Commissioners of Montreal, Que., duplex pump; the Gold Lion Brewery Co., Valleyfield, Que., simplex vacuum pump.

Personal

H. E. Pawson, has been appointed electrical engineer for Prince Albert, Sask. He was formerly with the Phoenix Dynamo Co., of Bradford, Eng., and more recently with the Appalachian Power Co.

J. F. H. Wyse, consulting engineer, 34 Victoria Street, Toronto, has been appointed organizer and engineer of the Ontario Safety League. He has, for a number of years, been associated with the Ontario Railway and Municipal Board in a consulting capacity.

Arthur Reid, recently elected Commissioner of Public Utilities, at Lethbridge, Alta., is a Newfoundlander. When a young man, he entered the shops of John McDougall & Co., Montreal, and served six years as a machinist apprentice. He subsequently went to Glasgow, Scotland, and for some time worked in the largest marine engineering shops on the Clyde. He then took to sea life for three and a half years, working as a marine engineer and was awarded a first-class certificate of the British Board of Trade. He returned to Montreal to the firm of McDougall & Co., and was employed as erecting engineer, making a specialty of electrically driven turbine pumps. It was while on this job he was sent to Lethbridge to instal the waterworks pumps, and his services were secured by the city.

Catalogues

The Canadian General Electric Co., Ltd., Toronto, have sent us a copy of bulletin No. A-4131, dealing with storage battery, industrial and mining locomotives, with special reference to the storage battery type, explaining its principal features. Illustrations are given of the various types made by the company, also locomotives in operation, together with views taken from assembly drawings.

The Simplex Manual.—On the press, for the Simplex Wire and Cable Co., Boston, is a 92-page booklet which "just fits the pocket" as well as the needs of every electrical man who has anything to do with wiring problems. It is full of tables and other information of all sorts about insulated conductors and other matters electrical, and is equipped with an unusually complete index. Printed on a fine thin paper, and bound with stiff covers, the book is to be distributed gratis to those who ask for it.

DIXON'S FLAKE GRAPHITE

The perfect lubrication afforded by this natural product in combination with oil or grease works high economies in the saving of power by the reduction of friction.

The fine, unctuous flakes build up a friction-reducing veneer over the bearing surfaces which prevents the metal-to-metal contact which causes wear and wasted power.

Use Dixon's Flake Graphite in your bearings and you will minimize your friction load and your bearing renewals.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS

TO THE STATIONARY ENGINEER WHO IS NOT A MEMBER OF THE C. A. S. E.

Have you ever seriously considered the necessity of mingling freely with your fellow-men whose life's occupation is the same as your own? If you have not, I would like to place before you the advantages which accrue to all thus associated.

We preach the doctrine of elevation of the Engineers through the medium of education.

By joining one of the subordinate associations of the C.A.S.E. you can gain knowledge of the character which is deemed so essential by successful practitioners of all the useful professions.

In all fairness I would ask you if an organization devoted to the calling at which you earn your daily bread is not entitled to special consideration from you?

STRATFORD, - - - ONTARIO

The Detroit "500" will not syphon

The Detroit "500" Air Compressor Lubricator gives constant lubrication under every condition of service. The rate of feed never varies when changing from pressure to unloading or when returning from unloading to pressure.

The Detroit "500" cannot be robbed of oil and cannot be affected by changing conditions in the cylinder.

This lubricator can be started and stopped without changing the feed adjustment, preventing both loss of time and oil when starting up.

The bullseye gauge and sight feed glasses are kept tight and won't break. This lubricator will withstand the roughest service.

BRANCH FACTORIES Montreal, Winnipeg

Hundreds of Engineers are asking daily what is

Perolin

From Germany

PEROLIN is the first and only METAL treatment for cleaning and preservation of the interior of boilers.

Boiler metal is everywhere and always the same, and is the ONLY proper thing to treat.

It is the ounce of prevention for NEW boilers, and the pound of cure for OLD ones.

NEW BOILERS can be put in a perfect state of preservation in from 15 to 30 days with PEROLIN, which will positively prevent scale formation, pitting and corrosion.

OLD BOILERS can be thoroughly cleaned of all scale in from 30 to 60 days, and also put in a perfect state of preservation.

PEROLIN has proved this in thousands of plants throughout Europe and this continent, and not in a single instance has it failed where directions have been followed.

When hearing of anything for the first time, especially when such extravagant claims are made for it, it is human nature to incline towards skepticism and disbelief.

BUT, when you can PROVE in your own plant, at our expense, and on your own terms, that the above statements are true, is it not good business judgment to ask us HOW?

If this appeals to you take it up with our firm, or write us for further information.

RETURN STEAM TRAP FOR FEEDING BACK HOT

Founded in 1878

Export

GREAT SAVING IN COALS AND WORKING EXPENSES.

INCREASED BOILER EFFICIENCY.

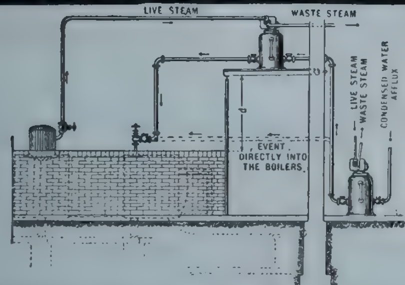
INCREASED LIFE OF BOILER.

MINIMUM OF BOILER INCRUSTATION.

SCHNEIDER & HELMECKE-MAGDEBURG Special Works for Steam Traps

CONDENSED WATER DIRECT TO BOILER, WITHOUT PUMP.

THE MOST RATIONAL



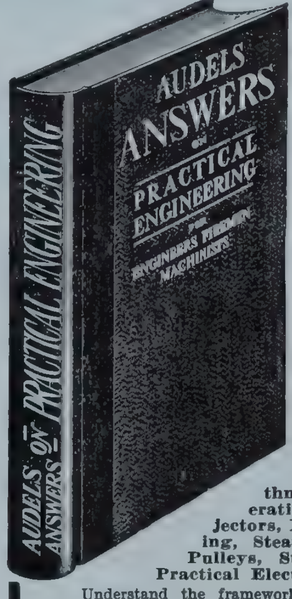
SELF-ACTING BOILER FEED

Direct Boiler Feed is also possible with one Return Steam Trap according to the situation.

Dominion Sugar Company, Ltd. We received your favour of the 5th inst. and noted its contents. To our great satisfaction we are able to inform you that your Return Steam Traps, are working excellently. We have now installed all four, which have worked faultlessly right away from the commencement. — One double Return Steam Trap suffices for conveying the condensed water from 6 Sperber drying apparatus directly back to the boilers. — *Since the Return Steam Traps were installed the feed pump for the boilers of the splitting-drying department has not been used.* — The saving in coals is considerable, since by aid of the Return Steam Traps we can now easily keep up full steam, whereas previously we had constantly to force the boilers to the utmost. After the experience gained with your condensed water Return Steam Traps we must admit, that no plant ought to be without the same. The feed pump has always been a unisance to us.

We leave it to your discretion to make whatever use of this you please.

Wallaceburg (Canada), Ont., Novbr. 22 nd, 1909.



AUDELS ANSWERS ON PRACTICAL ENGINEERING FOR ENGINEERS FIREMEN MACHINISTS
AUDELS ANSWERS ON PRACTICAL ENGINEERING

ENGINEERS

THIS book deals largely with the foundation principles which govern the practice of steam engineering. Nothing so soon condemns the applicant as want of knowledge of the every day practice and simple laws relating to the care and management of a steam plant.

No one is expected to know everything, but all are required to be familiar with certain facts which may be called "the beginning of things."

The lack of knowledge of the small things carries conviction of the same lack in the larger.

Plain facts, that you should know, are plainly explained in AUDELS ANSWERS ON PRACTICAL ENGINEERING, answers your questions on:

Air, Water, Steam, Fuel and Heat, Steam Boilers, Boiler Construction, Water Tube Boilers, The Steam Gauge, The Safety Valve, Properties of Steam, Installation of Boilers, Management of Boilers, Engineers' Law, Firemen's Law, Steam Engines, The Valve and Valve Gear, The Corliss Engine, Engine Arithmetic, Lubricators, Installation and Operation of Engines, Steam Pumps, Injectors, Feed Water Heaters, Steam Heating, Steam Traps, Belts, Gears and Pulleys, Steam Turbines, Refrigation, Practical Electricity, Elevators.

Understand the framework of which your work is but a cross bar. Know something of the cause of which your work is but an effect. Know something of the effect of which your work is the cause. And, above all, know why it is done one way and not another.

LEARN THE THEORY UNDERLYING THE WORK

PRACTICAL ENGINEERING contains 288 pages fully illustrated, handsomely bound and printed, and is in every way a first-class book.

FREE (No Duty)
EXAMINATION

Sign and mail the coupon, and it will bring to your plant a book of sterling merit, for free examination. You can have one week in which to dig out valuable information contained in its 200 or more pages.

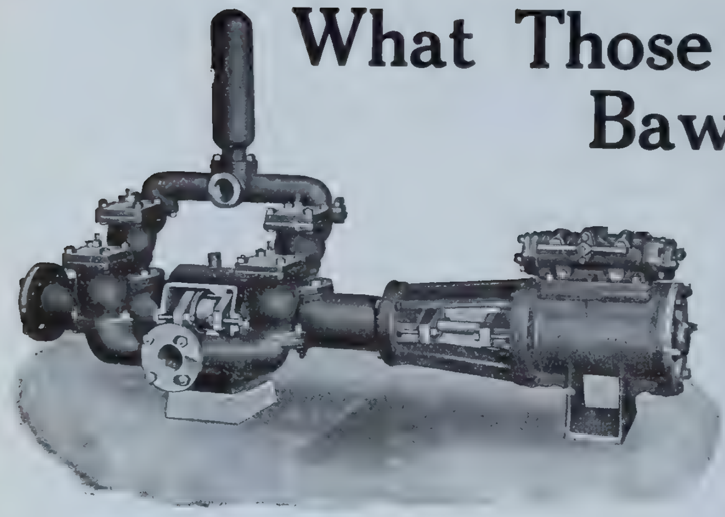
What Those Who Know Say Of Bawden Pumps



A User:

"I would never know I had a pump, as it needs no attention."

An Engineer Who Has Specified Them on a Number of Large Jobs:

"It is the best pump I ever saw."

An Engineer Who Made Tests:

"I don't know another pump made that will stand those tests like that pump."

A Large Manufacturer:

"It is the best made pump I ever saw and a credit to Canada."

A Contractor Who Uses Them on All His Jobs:

"I put them in, they start right off, and I never have a complaint, so they must be good."

A Prospective Customer:

"I called up the users you gave me, and will take your pump."

Pumps for all purposes.
Write for Catalogue and Calendar.
And learn why Bawden Pumps cannot Short Stroke or Bang.

¶ The Bawden Pumps are operated by the Bawden Patent Balanced Steam Moved Piston Valves, which insures a Full Stroke of the piston under all conditions. There are no outside rods to stick or get out of adjustment.

¶ The water valves have no screwed seats, but are driven in on a special taper and are held solid by brass stoppers through the covers, all parts made on jigs and faces machined, so no sheet rubber packing is required.

THE L.S. STARRETT CO. ATHOL, MASS. U.S.A.
PAT. MAR. 28, 1905
No. 104

STARRETT HIGH SPEED INDICATOR, No. 104. Value $1.00.

Given for two yearly paid-up subscriptions.

You May Have This Speed Indicator without Spending a Cent

if you are a subscriber to "THE POWER HOUSE." If you are not a subscriber, send in your own subscription together with two others, and the indicator you are entitled to will be mailed to you immediately.

To subscribers who send us two NEW yearly paid-up subscriptions we will send this $1.00 Indicator.

"THE POWER HOUSE' is designed to give Canadian Engineers, Superintendents and Power Users all the latest and best information in the engineering field. A little work among your engineer friends and acquaintances will earn for you this handy indicator without any trouble. Try it and see how easy it will be.

PUBLISHED MONTHLY AT $1.00 PER YEAR
Start in TO-DAY to earn one of these Handy Tools.

THE POWER HOUSE 143 University Ave., **Toronto**

WAKE UP, CANADA!

Why fire your boilers by old-fashioned costly hand methods when you might fire them by means of Bennis Automatic Machine Stokers and self-cleaning compressed air furnaces, or Bennis Automatic Chain Grate Stokers with the Long-Life-Link for use with water-tube boilers?

MARSH and AMERICAN
Pumping Machinery
For Every Service

Accompanying cuts illustrate an installation of Marsh and American Pumps made in the new C. B. & Q. office building in Chicago, Ill.

Marsh and American Pumps will also be found in many of the largest hotels and office buildings in the United States and Canada, including the McAlpin, Knickerbocker and Clarendon Hotels in New York City, the Brevoort and Blackstone Hotels in Chicago, the new Northwestern Terminal in Chicago, the new Michigan Central Terminal in Detroit, and the Simpson Department Store, Toronto.

Boiler Feed and Vacuum Pumps.

Elevator Pumps.

Marsh Pumps have been on the market for over 25 years, and continue to be the choice of discriminating engineers who desire the utmost in quality and reliability, regardless of first cost.

Our slogan: Simplex not Duplex. "To be simple is to be great."

HEAD OFFICE FOR CANADA - COLLEGE ST. (ST. HENRY), MONTREAL
TORONTO OFFICE, TRADERS BANK BUILDING

The call of the Industrial World of 1914 will be—

Maximum Efficiency

THAT means, essentially, the elimination of all needless **waste**—in time, labor and material. Back of your Shop Efficiency there must be the utmost **Efficiency in Your Power Plant.** That means both Fuel Efficiency and Steaming Efficiency—and you cannot have **either** with **inefficient boilers!**

No matter what experiments or expedients you may have tried, no matter what improvement you may feel that your present water-softening system has made—so long as you are bothered with scale, corrosion or other feed-water troubles **to any extent whatever,** there remains in your plant—**Boiler Inefficiency** which you can ill afford!

DEARBORN WATER TREATMENT steps in and makes good where other methods fail or only **partially** succeed, **because**—

It is, in each individual case, **a scientifically determined, definite treatment to meet exactly a definite condition!**

There is no guesswork about it, no blind reliance on the "law of averages," no "cure-all" compound of unknown ingredients and value, no illogical experimenting with mechanical action to meet chemical conditions—no uncertainties whatever, but an **advance assurance of complete efficiency** proven beyond doubt by the **satisfactory experience of thousands of power-plant owners all over the world** with the Dearborn Method.

This convincing assurance—of which ample proof is available if required; the recognized standing of this Company; its **Nearly a Quarter Century's Practical Experience** in dealing with feed-water problems; its superior equipment in the **largest, finest chemical laboratories in the world devoted to water analyses**—

All this invites your serious consideration and urges the good sense of availing yourself without further delay—of **our** facilities at **our** expense, in **learning the exact facts** concerning your feed-water troubles and the **correct** remedy.

Dearborn Chemical Company of Canada, Limited
TORONTO, CANADA
Office, 705 C.P.R. Building. **Factory, 1220-1230 Dundas Street.**

THE POWER HOUSE BUYERS' DIRECTORY

To our Readers:—Use this directory when seeking to buy power equipment or supplies. You will often get information that will save you money.

To our Advertisers:—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers:—A nominal rate of $1 per line a year is charged non-advertisers.

Full Particulars and Estimates Furnished

For All Water Power Purposes

If you have a water power you can use, the "Samson" wheel will develop that power most economically.

The high efficiency shown by this wheel in official tests proves its economy in the use of water, and shows what the wheel will do for you when working under your conditions.

It is easily installed, and when in operation is easily controlled.

The "Samson" is always sold on an absolute guarantee.

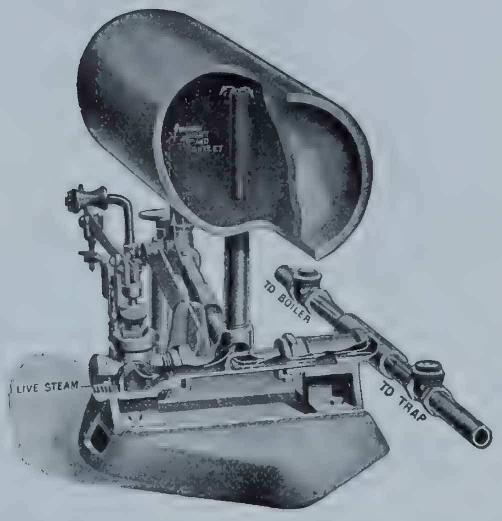
Morehead ~~Back to Boiler~~ SYSTEM



Conserve the Heat

that's in your condensation, the heat that costs you good dollars to put it there. Wasting it is equivalent to wasting money, and when you have to let your condensation cool down before your pumps can handle it back to the boiler, you're wasting heat — you're throwing money away.

Put in a "Morehead" Trap and let it return your condensation just as hot as it comes from the lines, let it conserve the heat and return it to your boilers —where it belongs—let it save you many dollars and give you a better, more efficient method of handling your condensation.

That it will do this we're willing to show you. You don't have to take our say so for it. Send us the word and we'll ship the trap and send a man with the necessary apparatus to prove our claims. And it costs you nothing unless you're satisfied.

Write to-day.

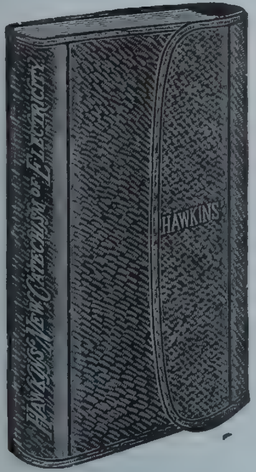
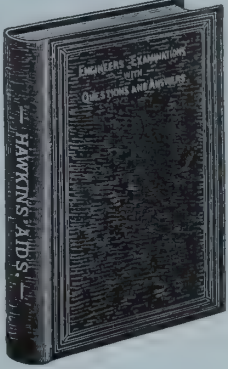
Books for the Engineer's Library



Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management.—$2.00



Engineers' Examinations

By N. Hawkins, M.E.

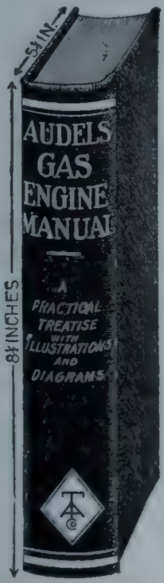
It presents in a condensed form the most approved practice in the care and management of steam boilers, engines, pumps, electrical and refrigerating machines, with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the steam engine and steam boiler.—$2.00.

Steam Turbines

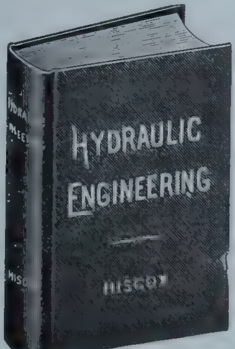
By Leland.

A reference work on the development, advantages and disadvantages of the steam turbine; the design, selection, operation and maintenance of steam turbine plants and turbo-generators. 135 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.



Hydraulic Engineering

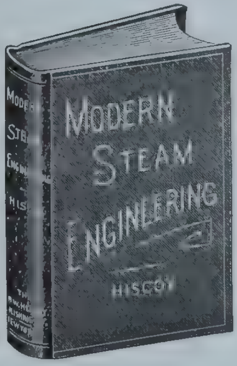
By G. D. Hiscox.

This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price, $4.00.

Compressed Air

By L. I. Wightman, E.E.

A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.00.



Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specially prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power, the steam turbine, electric power and lighting plants, etc. 450 pages, 400 detailed engravings.—$3.00.

Boiler Construction

By Kleinhans.

The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practical facts, such as line of riveting punches and dies, work done per day, allowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 334 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids and oils and the numerous appliances in which compressed air is a most convenient and economical transmitter of power.—Price $5.00.

Boiler Accessories

By Walter S. Leland, S.B.

Assistant Professor of Naval Architecture, Mass. Institute of Technology, American Society Naval Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economical operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.00.

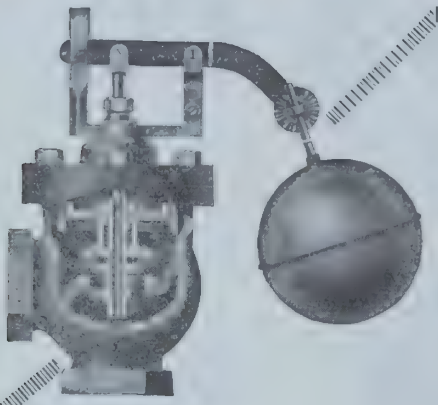
A Good Float Valve to Own



A PISTON, operating in a cylinder, that is packed with a leather crimp to prevent leakage is not a desirable construction for an automatic float valve. The packing causes friction and is short-lived. That means unsatisfactory operation and expensive maintenance.

The Davis Improved Float Valve

has an inner valve that is not packed in any way. It is operated entirely by pressure. The top member fits the cylinder loosely, so the inlet pressure can leak by and accumulate above the valve. The stem, which is directly attached to the float, forms an auxiliary valve that controls the action of the disc.

This valve makes an ideal automatic control for your water supply. It will always work properly without sticking. Its maximum cost for maintenance will be the few cents that you may have to spend sometime for a new renewable Jenkins type of disc. Let us send you a descriptive folder and quote on the float valves you need at this time.

— it will not stick,
— will not leak,
— has renewable disc and seat,
— has no leather cup packing,
— is operated entirely by pressure,
— has full pipe area,
— is strong and well proportioned,
— may be used as Balanced Valve,
— is made in globe and angle patterns.

Reduce Your Power Expense

WITH

Westinghouse Synchronous Motors

IN SOME applications, direct-connected Westinghouse Self-Starting Synchronous Motors have actually paid for themselves in a few years by the reduction they made in the power bills.

How is this done? These motors will raise your power factor. This means, if you generate your own power, directly increasing the capacity of your present generators, transformers and transmission lines; improving the voltage regulation, and raising the efficiency of your entire power installation.

Many central stations give better rates for high power-factor installations than for low ones.

Then, too, these motors require the least floor space, cost less to install than other types, and have the highest efficiency.

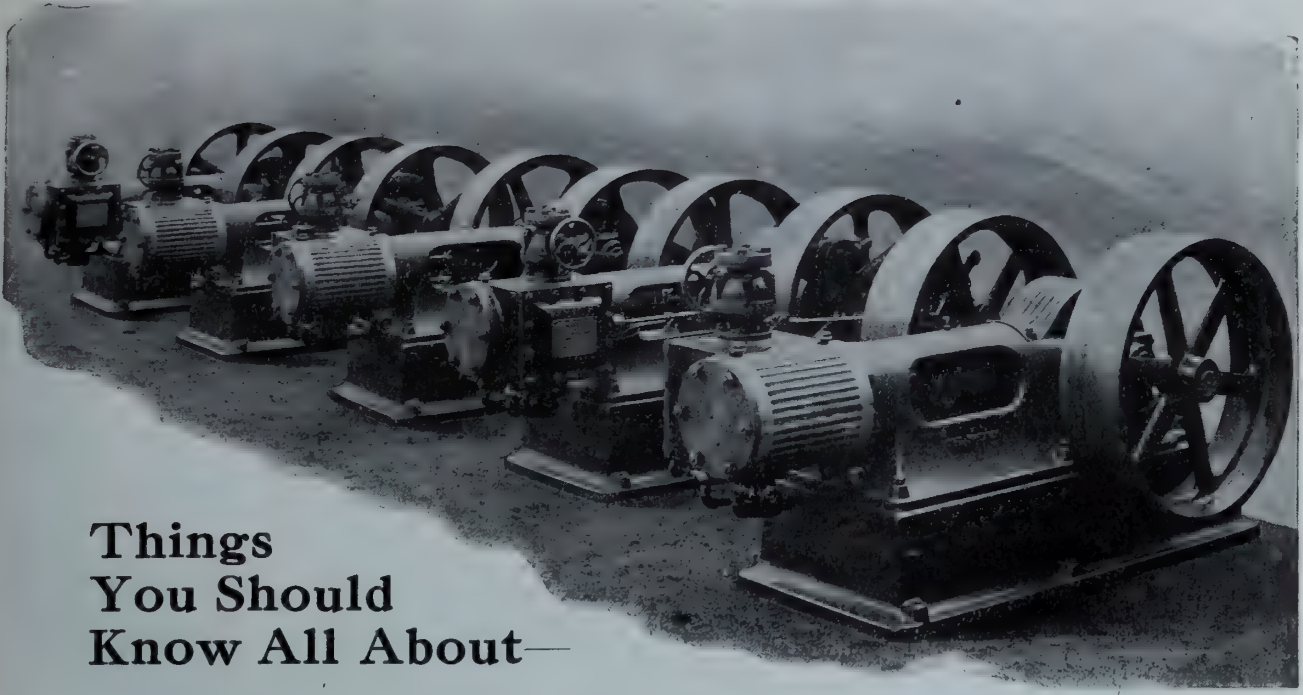
FOR SALE EVERYWHERE



Things You Should Know All About—

WHEN buying an engine there are some things you should insist on knowing:—that the engine you select is adapted to your work—that it has the capacity to stand up continuously to it—and that if anything does go wrong, the engine you have bought is backed up by a firm that will see that the damage is made good.

McEWEN ENGINES

are, first of all, sold on a basis of *satisfaction to the user.*

They are High-Speed Automatic Engines of the best type, built to stand up to hard usage. You will find few other engines giving the results you can get with the McEwen when it comes to delivering power, saving steam, and standing up to the work under a varying load. Furthermore, unless we are convinced that the McEwen will do your work—and *do it better than another engine,*—we will not advise you to buy.

We back up every McEwen we sell with a rock-bottom guarantee that covers performance and service, and although we have sold hundreds of these engines we have never yet been asked to redeem the guarantee. The engines are built to make it unnecessary.

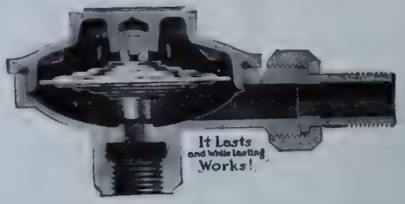
The McEwen Booklet is worth while—send for it.

The Waterous Engine Works Co., Ltd.

BRANTFORD, CANADA

GOOD and BAD HEATING

The heating season is now about half over. Will you kindly answer these questions (to yourself)?



Performs the functions of a Radiator Steam Trap perfectly and continuously. Eliminates water and air without loss of steam.

Have you had an item of expenses in labor and repairs for fixing traps that might have been saved?

Have you had any freeze-ups due to traps stopping up or traps leaking so much steam that the vacuum pump could not draw the water of condensation back properly and some return line froze up?

Have you had to admit cold water into the returns of the vacuum pump to condense steam that has wasted past the radiator traps?

If you have a gravity system of heating:—

Have you had to carry pounds steams pressure to secure circulation through your radiators?

Have you had to spend a great deal of time adjusting those spitting, sputtering air valves which either blow steam or water or keep the air in the radiator?

These will remind you of only a few troubles you may have experienced with your heating system.

Have you ever investigated the Dunham System, particularly the Dunham Traps?
Do you know that the Dunham Trap makes it possible to overcome all of these troubles?
Do you know that the Dunham Trap insures positive circulation of steam at a very low pressure?
Do you know that you can secure a Dunham Trap for sixty days' free trial, to convince yourself of our claims and if not satisfactory can be returned to us and not cost you one cent?

Well You Can! Write us for particulars of our "Try-Out Plan."

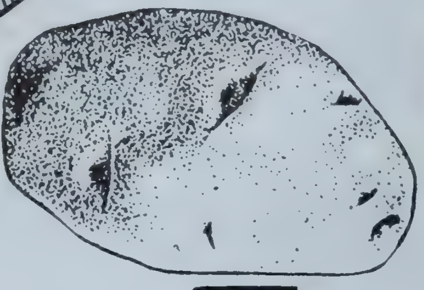
POTATO SCALE



BOILER CLEANSER

Would you feed your boilers on dollar bills? Would you order your firemen to fill up the stoker hoppers with nice, clean "greenbacks" fresh from the bank?

Of course you wouldn't!

You'd know that a dollar will purchase a great deal more calorific value in coal than it will give as feed under a boiler.

You wouldn't do this—you're a sane business man—yet you allow your boilers to accumulate scale that effectually prevents all but a small percentage of the heat you get out of your coal, from reaching the water it's intended for.

And you grouch at the cost, and go on "feeding with dollar bills."

Potato Scale Boiler Cleanser goes right to the root of this scale trouble—the feed water. Fed into your boilers in the manner and quantity we prescribe, it will quickly clean tubes and sheets of all adhering scale. And its continued use will prevent any new scale forming.

Send for a keg now. We guarantee it.

But do it now. Dollar bills aren't so very plentiful.

We sell 4 kinds of BOILER GRAPHITE
Get our prices.

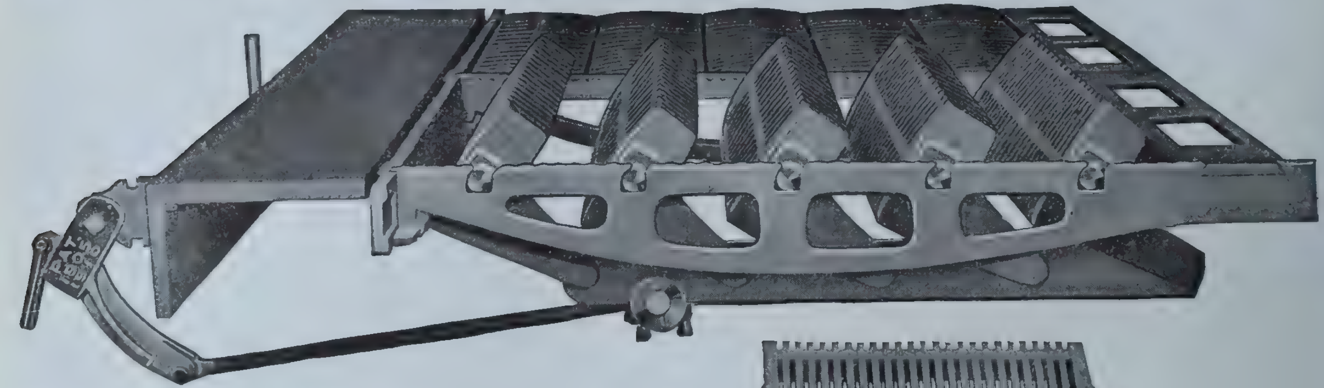
“The Cyclone” Shaking and Dumping Grate Bar



Cleaning Fires!

Raking red-hot clinkers from the mouth of a roaring furnace.

The smoke—the suffocating fumes—the sizzle and the hot sting of steam as you throw water on them.

That sort of thing's hard work—takes it out of you, makes you feel more dead than alive at the end of the day.

And as the "Cyclone" Grate will give you better steam and allow you to shake the clinkers through into the ash-pit by just pulling a lever—it's absolutely unnecessary exertion.

To shake the fire so gently that you just settle the uneven places; to shake it so vigorously that you clear all the clinkers out; to dump the whole fire into the ash-pit, you can do it all on the "Cyclone" by just pulling the lever.

And the patented lock prevents the bars from moving unless you do pull the lever.

Ask any of its users what they think about it. We're ready with the address as soon as you say the word.

Stop Blow-outs and Leaks in Pipe Lines by Using

GOETZE No. 2 ELASTIC GASKETS

If you start right now to renew with No. 2 ELASTIC GASKETS, you can steadily reduce your renewals until you have brought them almost to the vanishing point.

This is not a mere "claim"—it is backed up by a *guarantee*—in fact the strongest guarantee ever made by a gasket manufacturer.

Think what it means to re-gasket a joint so it will *keep tight for years,* instead of days or weeks. Think of the saving resulting in gasket costs, labor and shut-downs.

What No. 2 Elastic Gaskets Will Do

No. 2 Elastic Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight. Prevent leaks, blow outs and shut-downs. Will practically eliminate renewal expense for gaskets.

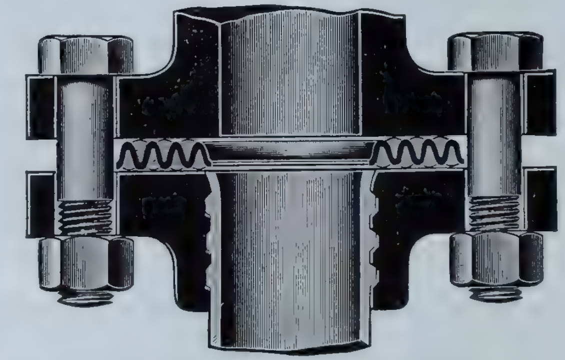
No. 2 Elastic Gaskets are for high pressure and super-heated steam lines, but owing to their indestructible nature, are equally adapted to *any and every condition* about a factory, mill or refinery.

The No. 2 Elastic Guaranteed

Every No. 2 Elastic Gasket is Guaranteed for 5 Years' Continual Service in the Same Joint

There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every No. 2 Gasket whether bought direct from us or through a dealer.

How No. 2 Elastic Gaskets are Made



These Gaskets are made of corrugated copper with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.

Goetze Gaskets are carried in stock by

Cheaper than P.P.P.
My Packing Looks like P.P.P.
This Packing Has Sliding Wedges like P.P.P.
The Packing That Prevents Some Friction.
DANIEL'S P.P.P.

Everybody's Doin' It

The best recommendations for an article are the number of imitations offered and the nearness (in appearance) of the imitations to the genuine, of course, making allowance for legal bars to making exact copies.

Another point, an ordinary or second-rate article is never imitated; the reason is that it takes the high reputation of the BEST to create a market for the "just-as-good" or "cheaper-than" kinds. The next step is to copy the advertising of the GENUINE article or, at least, to CLAIM for the counterfeits, results that the REAL actually give.

DANIEL'S ROD PACKING

P. P. P.

COIL, SPIRAL, RING

P. P. P. was the FIRST "sliding-wedge" rod packing. It has been on the market for TWENTY YEARS.

P. P. P. was the FIRST rod packing designed to PREVENT unnecessary FRICTION.

P. P. P. was the FIRST rod packing whose ADVERTISING laid stress on the relation of packing to FRICTION. And, until within a year or so, was about the ONLY advertising which covered this point.

P. P. P. was the FIRST and (to our knowledge) is the ONLY rod packing whose claims are backed with SCIENTIFIC PROOF.

The P. P. P. "Red Book" ("The Story of Some Friction Tests") was the FIRST book to go into the question of rod friction, and it is the text-book from which much of the material has been secured to advertise imitations of the ORIGINAL "sliding-wedge" packing.

A little time devoted to the study of our RED BOOK will make you a Packing EXPERT; give you a better theoretical and practical knowledge of the relation of various types of packing to FRICTION than is possessed by most college-graduate Mechanical Engineers. Size 5 x 7 inches, 44 pages, 12 diagrams, indicator cards, etc.; 35 illustrations, bound in red. More than 100,000 copies have been issued. It is FREE, if you ask for "Book 24-B." Write TO-DAY.

Insist on getting the box with the big RED D (see illustration) and the signature of C. A. Daniel.

Ever Shut Down on Account of a Burned-out Bearing?

A BOWSER
Lubricating System Would Prevent This

If so, there is something to be remedied in your power plant.

Putting up with "out-of-date" oiling systems in your engine room in this day and age of progress is a big mistake.

It means that you and your stockholders are depriving yourselves of a Necessity that most of your competitors are enjoying.

For you can buy a small oiling system, intended for use in small plants which have comparatively small amounts of oil drips to handle.

Or, the highest grade oil filtering and circulating system for the largest power plant, at a price that you will save in a year out of what is now dead loss.

We have supplied oiling systems that pay 100% dividends in many plants, ranging from 50 H. P. up to 500 H. P. or more, in fact, wherever two gallons or more of oil per day are used.

A Bowser Filtering System is a Necessity

An oiling system that will reduce friction 5% will effect savings in one year's time sufficient to pay the entire cost of the installation, and if run 24 hours a day it will effect even more.

For example:—A list of savings are here tabulated, using a sample plant as an illustration:—

Three 500-kilowatt engines, run 20 hours per day, average, full load, 12 hours, 300 days per year. Coal consumption, 10 pounds per kilowatt hour. Coal cost, per ton, $1.80. Unloading, firing, cleaning ashes, cleaning boilers, etc., 40c per ton.

What our systems save for the large plant they will show in proportion in the small plant. No matter whether you use two gallons or two hundred or more gallons of oil, write now for descriptive literature of the

Bowser Safe Oil-Filtering Systems

Installed, it assures every member of your power plant a 365-day guarantee of freedom from worry, and at the same time increases your output and dividends.

Remember the name

BOWSER
ESTABLISHED 1885

stamped on the system, guarantees Service, Confidence and the Knowledge that 28 years of experience are incorporated in every system. You can install the outfit yourself from our blue prints and from our simple directions accompanied by the blue prints, or we will install for you, thus relieving you of every care.

Coal cost per year:

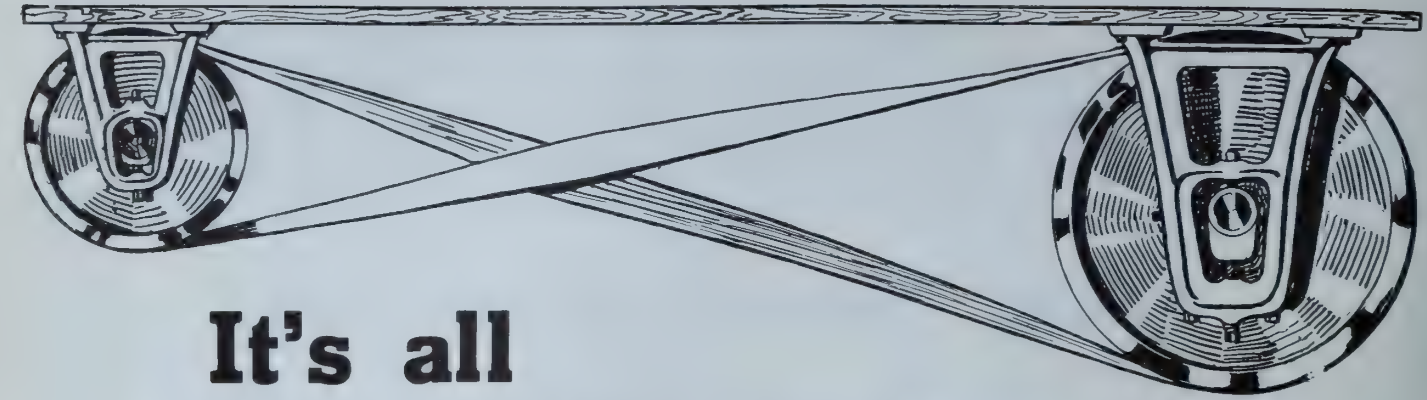
BRONZE TO BRONZE AT THE JOINT
CANNOT RUST OR CORRODE



It's all in the Leather !

Running round a twelve-inch pulley, revolving at 300 revolutions a minute, means that every part of the belt is folded up and straightened out 18,000 times an hour.

And this is the reason that belts made of inferior parts of the hide, or of leather tanned by a process that destroys its animal elasticity, will not stand up to this gruelling service without quickly showing signs of distress.

Modern science has not been able to devise any quick method of tanning leather, which will yield a product comparable with that obtained by the old, slow British oak-tanning process—which will produce a leather, thoroughly tanned, yet retaining all the "life" of the original rawhide.

Therefore on your most difficult drives put

D. K. McLAREN'S

Genuine British Oak-Tanned

LEATHER BELTING

every foot of which is guaranteed made from a selected part of the hide, tanned by the only process that retains all its life.

No necks, bellies, or shoulders are allowed to enter into the composition of D. K. Maclaren's belting. The very finest part of the hide only is used, all the rest being discarded.

And before we make it up into belts we thoroughly stretch every inch of it—so in service they will transmit the maximum of power, with a minimum of slip, and will require tightening very seldom.

Let us put you in touch with a few out of many satisfied users—and be guided solely by what they tell you.

We **know** what the result will be,—**so write us now.**

This mark on a belt is a guarantee of the sort of belt-service you want.

Educational Talks On Leather Belting by the

GRATON & KNIGHT MFG. COMPANY

WORCESTER, MASSACHUSETTS

To attain maximum efficiency and economy in your plant it is absolutely essential to know all possible about belting.

Leather Belting correctly installed and properly cared for is the most efficient and economical transmission medium.

Yet it is a well known fact that belting receives very little attention for such an important factor. For this reason we intend to publish in this paper a series of educational talks on belting, its selection, its care, etc. They will be "straight from the shoulder" talks, plain, instructive and authoritative.

Our Engineering Department is at your service, consult it freely concerning your transmission problems.

1851 G&K

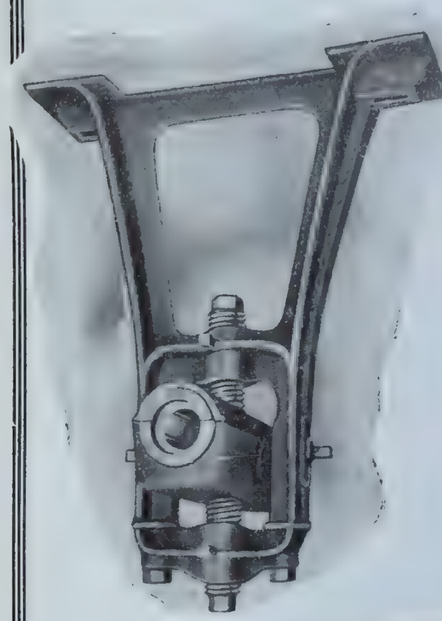
ELMIRA

Ball & Socket HANGERS

For MAXIMUM Service

Wood Split PULLEY

AND BIG REDUCTION IN POWER TRANSMISSION COST



The "Elmira" Ball and Socket Hanger

is exceptionally strong and heavy. In this hanger a union system of oiling is employed, a combination of centrifugal and capillary attraction, effected by tempered steel rings and woven cotton distribution of lubricant, and precludes the slightest possibility of "Dry Bearings" so long as any oil remains in the reservoir or dry chamber, one filling of which should last from six to twelve months.

The "Elmira" Wood Split Pulley

You can use an "Elmira" Pulley any place that a leather belt will give satisfaction, and know that what any good pulley will do, it will do, and more.

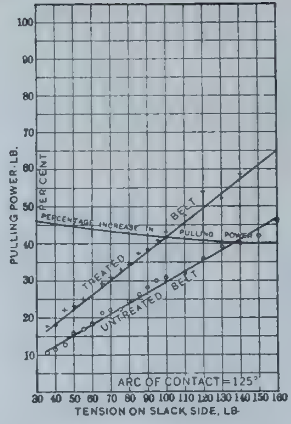
This pulley stands the hardest and most severe conditions. It is nailed throughout. The arms are tenoned into rim and dowelled there.

Absolutely guaranteed.

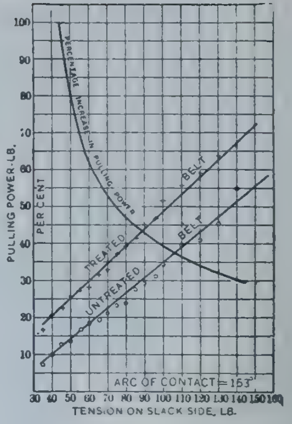
It will be much to your interest to let us furnish you with our illustrated catalog. Write for it to-day.

Large and complete stocks carried at Elmira and by The A. M. Ellicott Co., 301 St. James Street, Montreal, Que., Sole Eastern Agents.

Elmira Machinery & Transmission Co., Ltd.
ELMIRA, CANADA



40 to 46 per cent. increase.



30 to 100 per cent increase.

These Curves Show the Increased Pulling Power Produced by Cling-Surface.

And as they were plotted by Robert Thurston Kent, M.E., you can know they are authoritative.

Mr. Kent tested two new belts—one treated with Cling-Surface, and the other not. To make the test perfectly fair, both belts were first driven side by side in a New Jersey factory. Then, by means of a testing frame built especially for the purpose, some weights, and a polished rigid pulley, the comparative tests indicated by these curves were made.

Note that no matter how large or how small the arc of pulley contact and no matter what the tension on the slack side, the Cling-Surface curve is **always on top**, the advantage of the Cling-Surface-treated belt varying from 14 to more than 100 per cent over the untreated belt.

The complete statement which Mr. Kent has prepared covering these tests is now printed in booklet form. If you wish, as you should, to improve economy in and in connection with your belts, we will be pleased to mail you a copy.

Cling-Surface stops slip, makes belts pliable, easy-running, and long-lived; waterproofs, and reduces friction. Best of all, it accomplishes this, and more, too, without making the belt sticky or leaving any deposit on the belt surface.

Cling-Surface is used all over the world with equal success—in the dryest, wettest, hottest and coldest climates.

Your order or inquiry will have our best and quickest attention. We quote f.o.b. Toronto.

For Services Rendered

Practically every testimonial that we receive and publish is a grateful acknowledgment for relief given, and services rendered by MAGNOLIA METAL on troublesome bearings where other babbitts failed.

It is on such a firm foundation that our business is built here, there, everywhere.

E. K. WOOD LUMBER COMPANY

Los Angeles, Cal., May 2, 1913.

Dear Sirs:—

Kindly allow me to congratulate you on the quality of your metal, which has given me the most perfect satisfaction. About 18 months ago I placed in my mill a 30″ x 6″ high-speed planer (the top head speed 4100), 2 7-16″ x 11″ bearings. From the first this planer gave me a great deal of trouble. The bearings burned out thirty days after I placed the machine in the mill. I bought a babbitt at 42 cents a lb. (being good babbitt) and repaired the machine with it, but with poor results (I am a mechanic of thirty-two years' experience). I then bought Copper Hardened Babbitt, which still did no good. On January 1st, 1913, I bought Magnolia Metal, and remetalled the bearings, and have been running ever since, eight and one-half hours out of the nine, and have had no trouble at all. Commenting upon the head 7″ diameter, 30″ length, with six knives and two 7-16″ x 11″ bearings, weight almost 900 lbs., in other words, 170% running balance, requires FIRST-CLASS BABBITT, and hereafter I shall use no other kind, for I must say, that Magnolia Babbitt gives perfect satisfaction.

Respectfully yours,

(Signed) L. EICHWALD, Mill Supt.,
E. K. WOOD LUMBER COMPANY.

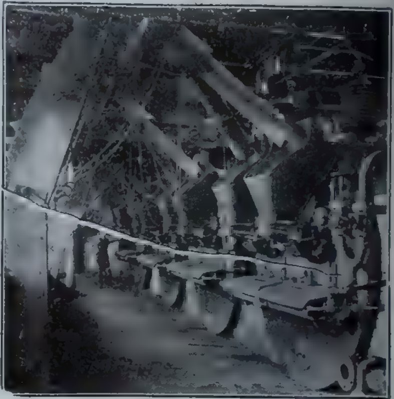
Bennis" New Long Link Chain Grate Stokers.

Bennis Chain Grate Stokers
Bennis Machine Stokers

with Patent Self-Cleaning Compressed Air Furnaces for Water Tube and Horizontal Return Tube Boilers.

Bennis Machines are supplying over 3½ Million Horse Power and are saving Millions of Dollars a Year.

"BENNIS" machines feed the fuel where the fire requires it, keep the fire at a nicely calculated distance from the boiler front, and responds to varying loads with a rapidity that is the outcome of good design. They ensure the maximum results from the boilers, reduce the fuel bill, and keep clean chimneys because they ensure good combustion.



For Cheap Steam without Smoke install "Bennis" Machine Stokers and Elevators.

"Bennis" stokers are not simply made from one design and adapted to meet the requirements of different types of boilers, but are specially designed for the various types, constructed with the greatest care and fitted to meet individual conditions.

The greatest economy is achieved when Bennis elevating and conveying plant feeds the stokers. "Bennis" coal and ash-handling plant has acknowledged advantages over other types, not only in design and construction, but in the small amount of power required to operate it effectually.

LUNKENHEIMER POP SAFETY VALVES

Iron Body
Spring Encased

4-43

These valves are **economical** because they will **relieve only enough steam to reduce excessive pressures.** They can be positively relied upon to **operate promptly** and will not chatter or pound themselves to pieces.

They can be regulated to reduce the pressure only one pound, if such close regulation should be desired, and adjustment of the pop and pressure can be made from the outside of the valve.

All parts subjected to wear are renewable. Either **Brass or Iron Body Valves** can be had, with encased spring or spring exposed.

For durability and reliability, **LUNKENHEIMER POP VALVES** have no equal.

Specify and insist upon having genuine **Lunkenheimer make.** Do not accept substitutes—they are never as good as the genuine.

Your local dealer can furnish them; if not, write us. Write for catalogue.

Instruments for Power Plant Testing

ARE you running YOUR Boiler Room—YOUR Engine Room—or the Power Plant under YOUR control on a "maximum of efficiency with minimum expense" basis? If not, you are not working for the interests of your Boss—and incidentally not for your own interests.

Of course, to run things on a systematic basis, you must have proper testing instruments. That is where we come into the story.

Since 1850—nearly 63 years ago—the House of Schaeffer & Budenberg have manufactured "Instruments for Power Plant Testing"—Instruments of Quality and Precision. And with the knowledge accumulated during this time, we have maintained a SERVICE DEPARTMENT to solve YOUR problems.

Our Catalogs and Our Service

You should have a set of our catalogs. They are mighty interesting and very instructive. Why not write for a set NOW? And while you are writing, think—isn't there some problem we can solve for you? Tell us your troubles—we can help you. **It costs nothing.**

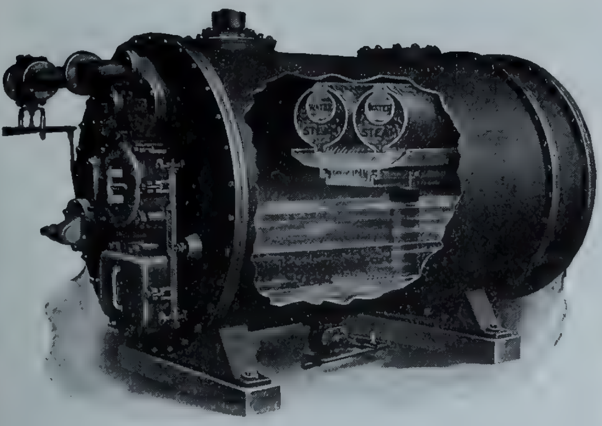
NATIONAL TRUST BUILDING - TORONTO



Contact Pipes.

IN THE

NATIONAL

DIRECT CONTACT FEED WATER HEATER AND PURIFIER

the water is first heated by surface contact and then brought to maximum temperature by actual contact or mingling with the steam. This is the feature which distinguishes the National from all other open heaters.

The contact pipes are double. From the inner, the water overflows the port at the top, and passes around the large pipe as a thin film. It is broken into fine spray at the bottom. The steam leaving the outer pipe at the bottom passes through the spray and finally all water and steam are in direct contact above the filter bed.

Other features explained in Catalog No. 2

Your workmen's eyes and nerves

need to be kept in good condition to turn out the best quality work.

An inefficient light makes bad eyes, and is a big strain on the nerves.

By placing a **Sunbeam Mazda Lamp** in every socket your lighting system will be efficient—you will GET THREE TIMES THE LIGHT OF THE ORDINARY CARBON LAMP at the same electrical consumption, and insure quality production.

Sunbeam Mazdas are as rugged as any Carbon Lamp—they will burn in any position.

Fully guaranteed—we ship promptly.

Nonpareil Corkboard Insulation

for

COLD STORAGE WAREHOUSES, BREWERIES, PACKING HOUSES, ABATTOIRS, CREAMERIES, Etc.

Secures the highest insulation efficiency by its purity.

There's nothing in it but that best of insulating agents, PURE CORK.

That is why it was USED EXCLUSIVELY IN THE FRONTENAC BREWERIES, MONTREAL, where the highest efficiency was demanded.

NONPAREIL, CORK COVERING FOR BRINE, COLD AND ICE WATER PIPES also gives the greatest service.

NONPAREIL HIGH-PRESSURE COVERING,—a new and better steam pipe and boiler covering, made of Nature's best heat-insulating material—diatomaceous earth.

NONPAREIL INSULATING BRICK, for Boiler Settings, Bake Ovens, etc.

THE KENT COMPANY, LIMITED

Montreal, Que.

J-M PURE CORK SHEETS cut refrigerating cost 23%

Here's the proof.

After a few years' service a building with an exposed area of 40,000 sq. ft., insulated in the old way with mill shavings, usually requires 3,500 tons of refrigeration to maintain a temperature of 30 degrees during the eight Spring, Summer and Fall months when the average outside temperature is 80 degrees.

Insulated with J-M Pure Cork Sheets it requires only 2,666 tons to keep the temperature at 30 deg. A saving of 833 tons, or 23.8% of refrigeration.

At 50c. per ton this represents a saving of $416.50 in one season.

And the increase in storage capacity made possible in a building of this size by J-M Pure Cork Sheets means an additional increase in profit of $1,320.00 for the same term, figuring storage space at 8c per cubic foot per season.

Unlike old-fashioned insulation, J-M Cork Sheets are not affected by moisture —never rot or crumble—and last as long as the building in which they are installed. And they are approved by the Fire Underwriters.

You can reduce your maintenance cost and increase the storage capacity of your plant. Let our engineers show you how. It won't cost you a cent or place you under the slightest obligation for the information. Write Nearest Branch.

THE WORLD'S LARGEST PLANT for the Manufacture of Ice Making and Refrigerating Machinery

Being Made Larger to Accommodate the INCREASING DEMAND FOR ITS PRODUCTS

Owing to the steady increase in the demand for YORK Ice Making and Refrigerating Machinery it became necessary, recently, to again enlarge our Plant. An entire City Block, comprising the property of The Hench & Dromgold Co., is our latest acquisition.

No Company can grow as we have grown unless its output possesses merit. Each year, during the past decade, has shown an increase in our annual sales. We say this not boastfully, for we realize that this very favorable showing is due, in a large measure, to the loyalty of those who think well of YORK Products.

The World's Largest Plant—but our complete modern factory equipment enables us to give your smallest order the most careful and prompt attention, as well as to make the quickest possible delivery of the largest orders.

Think it over. We believe you will find it profitable to cultivate an acquaintance with YORK PRODUCTS.

YORK MANUFACTURING COMPANY, York, Pa.

Your Valves play a most important part in your Power Plant Equipment.

FAIRBANKS VALVES

should be used on all your high-pressure lines.

Tested under the most severe conditions, their great durability and strength enable them to give the greatest service.

High-class workmanship, and improved design, by Valve Experts, render them absolutely dependable at all times.

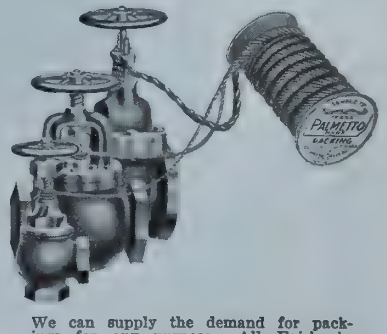
The Fairbanks Renewable Disc

the principal feature of Fairbanks Valves, owing to its composition of long-fibred Asbestos and rubber, with a special binding process, is long lived, unbreakable, tough, yet sufficiently soft to cushion perfectly with the valve seat. The RAISED ROUND SEAT is practically self-cleaning, its shape preventing the lodging of foreign substances which might injure or destroy the seat.

FAIRBANKS DISCS are easily renewed; simply remove the valve bonnet and slip a new disc upon the end of the spindle.

Fairbanks Valves are fully guaranteed, and regular weight valves are tested to 300 lbs. hydrostatic pressure.

Specify these valves for all your high-pressure lines, and be certain of getting the highest valve efficiency.



We can supply the demand for packings for any purpose. All Fairbanks Valves are packed with PALMETTO twist packing. You will save a lot of trouble with your valves if you do likewise. You know then that they will remain tight.

Power Equipment of the Frontenac Brewery, Montreal

Staff Article

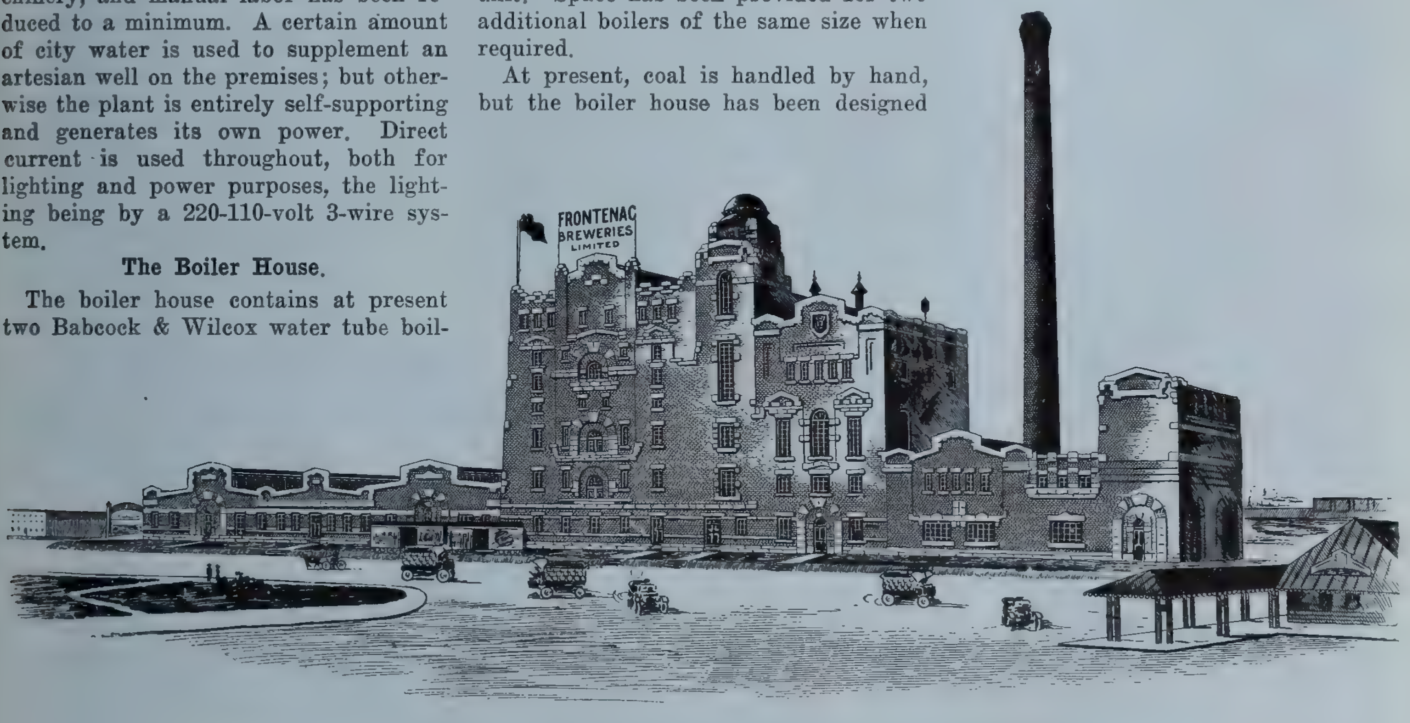
The directors of this brewery have spared neither money nor pains to secure the best and most modern equipment possible. The plant has been built on the unit system, so that enlargement to twice its present size can readily be accomplished when desired. Though not so large, it is quite as well equipped as any of the huge breweries in the United States; and the beer is produced under the most sanitary and hygienic conditions possible. The plant has been specially designed to eliminate all "lost motion," and manual labor has been reduced to a minimum by the installation of automatic machinery and other labor-saving devices.

THE plant of the Frontenac Brewery, Ltd., Montreal, which recently went into operation, is said to be the largest and most up-to-date brewery in Canada, and a visit to it paid by "The Power House" certainly served to convince one of the substantial nature of the claim.

The building stands on a site of 3½ acres at the north end of the city and was designed by Mr. Paul Ott, New York. The Canadian Stewart Co., Ltd., were the contractors for the building. The various departments all lie parallel with one another, a railway siding running across the ends of each. These departments, starting from the south end are:—Boiler House, Engine Room, Brew House, Mill House, Storage Section, Wash House, and Bottling Section. All are equipped with the latest type machinery, and manual labor has been reduced to a minimum. A certain amount of city water is used to supplement an artesian well on the premises; but otherwise the plant is entirely self-supporting and generates its own power. Direct current is used throughout, both for lighting and power purposes, the lighting being by a 220-110-volt 3-wire system.

The Boiler House.

The boiler house contains at present two Babcock & Wilcox water tube boilers of the latest forged steel construction, set in one battery. Each boiler is rated at 200 H.P. and contains 2,010 square feet of heating surface. The working pressure is 125 pounds, although the design is good for 160 lbs. They are equipped with Babcock & Wilcox patent mechanical chain grate stokers, the two stokers being driven from one 2-h.p. steam engine. Natural draft is provided by a Kellogg radial brick chimney, 150 high and 6 feet internal diameter. Practically no smoke is ever given off from the chimney, a fact which speaks well for the perfect combustion obtained with the stokers, in spite of the fact that the fuel used is soft coal slack.



GENERAL VIEW OF FRONTENAC BREWERY, MONTREAL.

The boilers are equipped with Foster superheaters, giving 100 degrees of superheat, and are covered with 2 inches of 85 per cent. magnesia insulation, this work having been done by the Canadian Asbestos Co., Ltd., Montreal, who also did all the pipe covering in the engine room. In winter, one boiler is capable of supplying all the steam required by the plant, the other forming a stand-by unit. Space has been provided for two additional boilers of the same size when required.

At present, coal is handled by hand, but the boiler house has been designed to allow of overhead bins and elevating machinery and these will eventually be installed.

The boilers are fed by two 5-7-12 Weir direct-acting feed pumps supplied through Peacock Bros., Montreal, each capable of feeding both boilers, when running at fifteen double strokes per minute. The pumps were sold under a guarantee to run as slow as four double strokes per minute without stopping. This is, of course, equivalent to a piston speed of only 8 feet per minute. The pumps are enclosed in a chamber situated in a corner of the boiler house, with the object of protecting them from grit and dust. This chamber has a roof of reinforced concrete, on top of which stands a Cochrane open-feed water heater made by the Harrison Safety Boiler Works, Philadelphia, Pa. This is connected to the main 14-inch exhaust header, and brings the feed water up to a temperature of about 210 degrees Fah. All high and low pressure drips throughout the plant are returned to the heater by Strong and Bundy traps.

The use of a Cochrane heater of this type eliminates the necessity for an independent separator for the main exhaust. A large separator forms an integral part of the heater and serves to purify all the exhaust steam brought from the engines and pumps. The heater is covered with a 2-inch layer of 85 per cent. magnesia insulation, this work having also been done by the Canadian Asbestos Co., Ltd. The main steam header above the boilers is 12 inches in diameter, and from it a 10-inch pipe leads to the engine room and a 6-inch pipe to the brew house.

The Engine Room.

On entering the engine room, which is divided from the boiler house by the usual fire wall, one is immediately struck with the extremely orderly appearance and fine finish everywhere to be seen. The various power units are painted a crimson lake color, nicely lined in gold. All steam pipe flanges and all exhaust pipes, where not covered, are painted with aluminum paint. The engine room has a Terazzo floor laid down by the Dominion Floor & Wall Tile Co., Montreal. This flooring consists of cement and colored marble chips and has a handsome appearance, combined with a smooth finish. Large windows fitted with Fenestra steel sash give the room exceptionally good natural lighting. The walls have a 5-ft. dado of white glazed tiles, above which they are painted a pale green. All engine foundations are finished off with white enameled brick and tiles, so that the general appearance of the room is very fine.

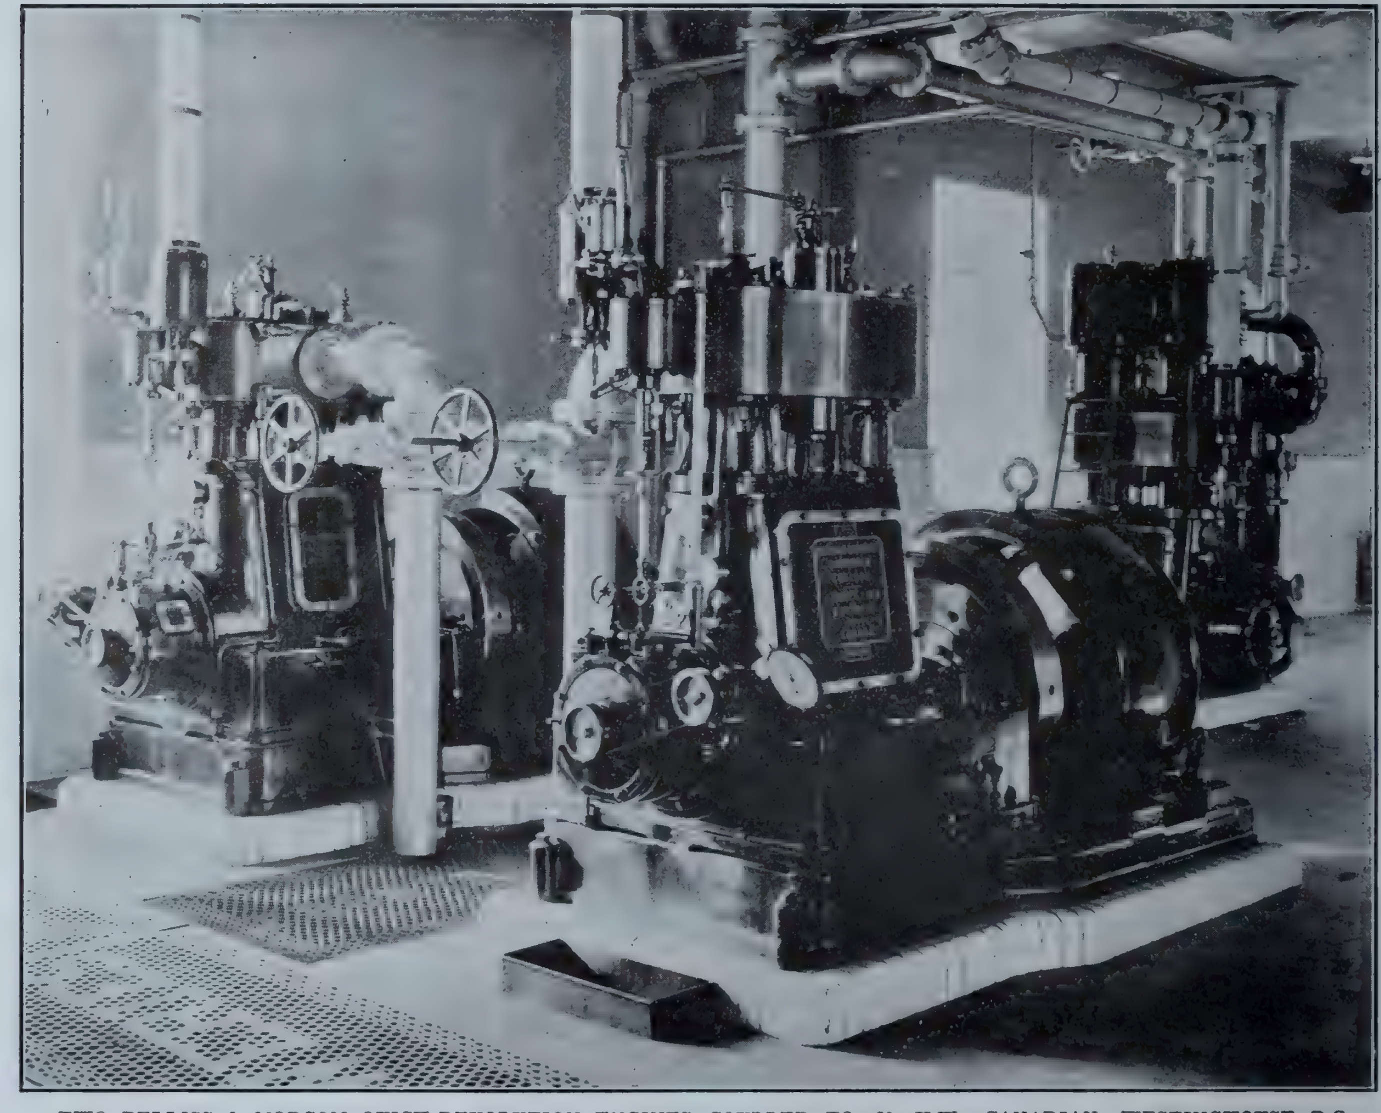
C. H. LLOYD, CHIEF ENGINEER.

Nor is it in this department only that appearances have been studied. The same high degree finish is to be found throughout the brewery, and is an excellent advertisement, as visitors can hardly fail to be impressed with the cleanly and sanitary surroundings amidst which the beer is brewed.

Refrigerating Machinery.

The refrigeration plant is an establishment in itself. This equipment was installed by the Vilter Manufacturing Company, Milwaukee, Wis., and has a total daily capacity of 280 tons of refrigeration. The two large steam-driven compressors, the ammonia condensers and the arrangement of the ammonia pipes and connections are of the latest design, and form a fine example of the progress that has been made in refrigerating machinery in the last few years.

The duplicate refrigerating units are located at the south end of the engine room. Each consists of a Vilter heavy duty ammonia compressor direct connected to a Vilter simple Corliss engine.



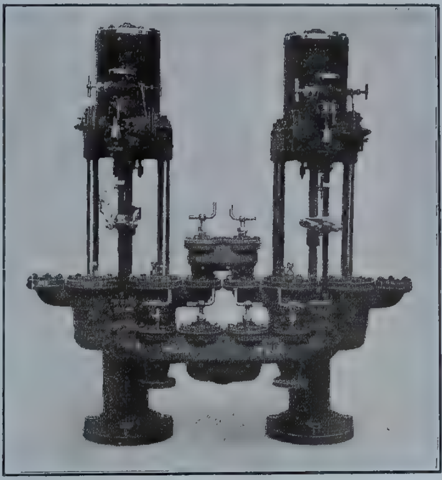
TWO BELLISS & MORCOM QUICK-REVOLUTION ENGINES COUPLED TO 60 K.W. CANADIAN WESTINGHOUSE D.C. GENERATORS.

The two units are built right and left-hand and each is rated at 140 tons capacity. In fact, when running at 60 r.p.m., with 20 lbs. suction pressure and 175 lbs. condensing pressure, each compressor delivers 142 tons of refrigeration.

The Corliss engines are of the heavy duty type with single cylinders 22 inches bore by 42 inches stroke. The cylinders are cast of a hard close-grained semi-steel mixture and are protected from heat radiation by a covering of plastic magnesia encased in neat laggings of planished steel secured by polished angle iron corner straps. The back cylinder heads are covered with highly polished false heads.

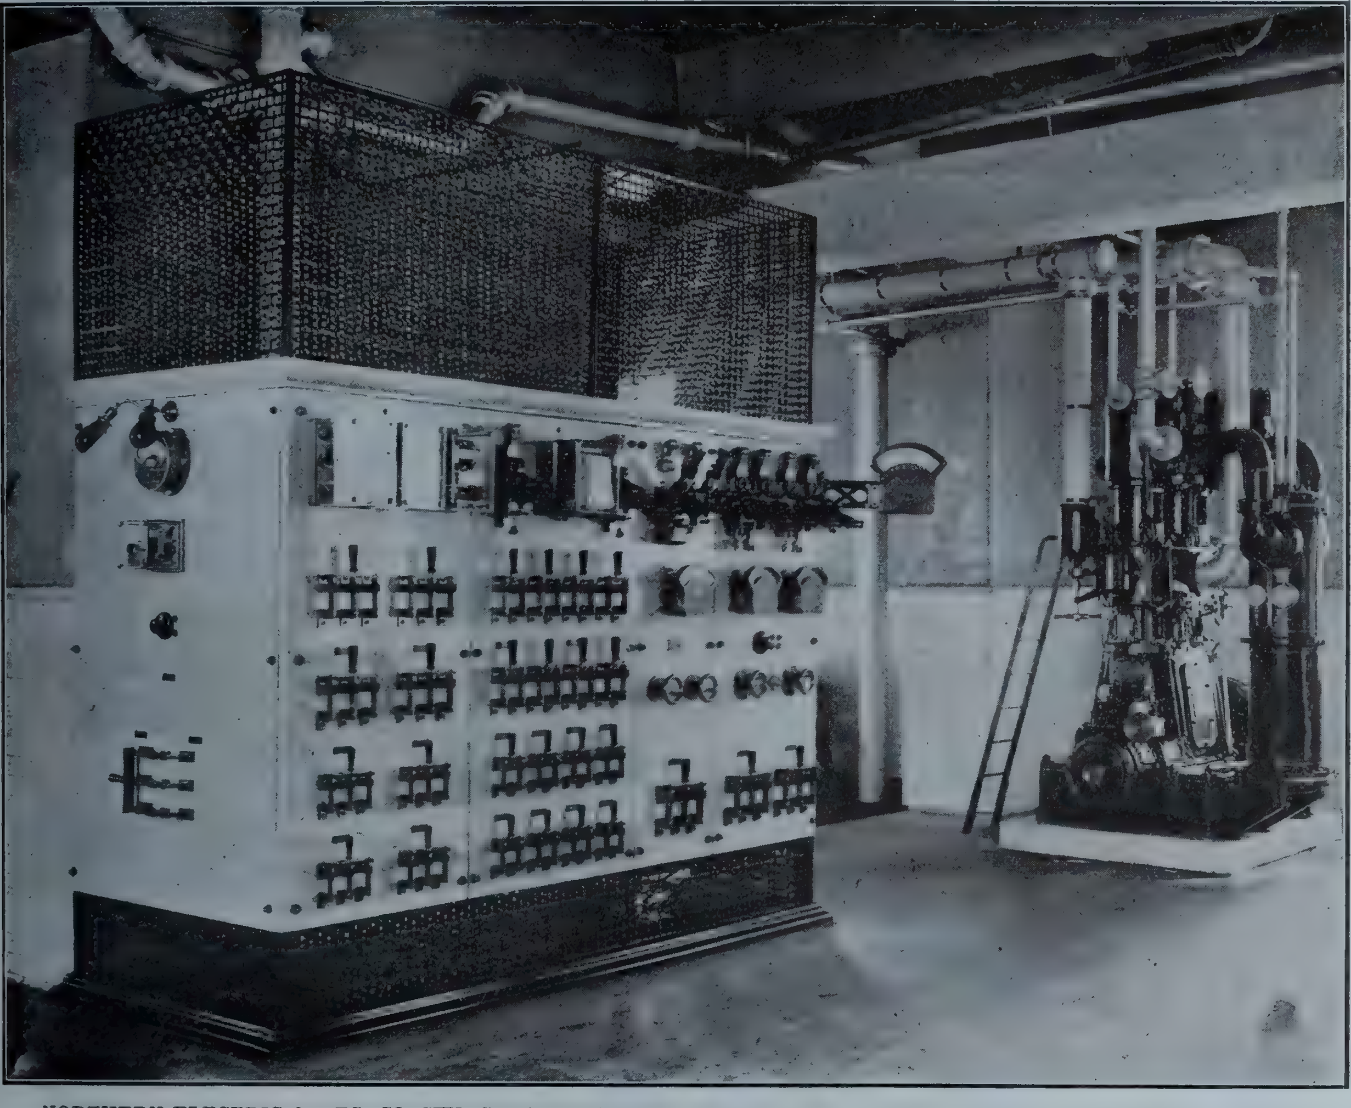
The ammonia compressors are of the horizontal double-acting heavy duty type. The compression cylinders are $17\frac{1}{2}$ inches diameter by 34 inches stroke. They are cast from a similar mixture to the steam cylinders and are pressed into the housings of the compressor frames in such a way that the latter form water jackets round each cylinder. The compressor heads are made semi-spherical, this form permitting the use of valves of large area. The valves are spring balanced and are so cushioned as to be nearly noiseless in operation. The suction valves are provided with special safety collars.

The flywheels of the two machines are made in half sections bolted together. Each wheel is 14 feet in diameter and weighs 20,000 lbs. One of the wheels has a 38-inch crowned face for a belt drive, so that the compressor may be run by an electric motor in future if desired. The foundation of this machine is all prepared for the reception of a motor, it merely being necessary to remove a rectangular brass-bound section of the engine-room floor to make room for the placing of the latter.



"WEIR" BOILER FEED PUMPS.

The ammonia condenser is of the atmospheric type and is located in a compartment above the engine room. Part of this upper room is used as a machine shop and pipe-fitters' shop. The condenser consists of a battery of eight coils, each coil being 20 pipes high by 20 feet long. The coils are constructed of 2-inch and $2\frac{1}{2}$-inch full weight wrought iron lap-welded pipe and are of special construction designed for the particular local water requirements. Each coil of the condenser is fitted with an individual shut-off valve, enabling any section to be cut out without interfering with the



NORTHERN ELECTRIC & MFG. CO. SWITCHBOARD ON THE LEFT. AND BELLISS & MORCOM HIGH-SPEED AIR COMPRESSOR ON THE RIGHT.

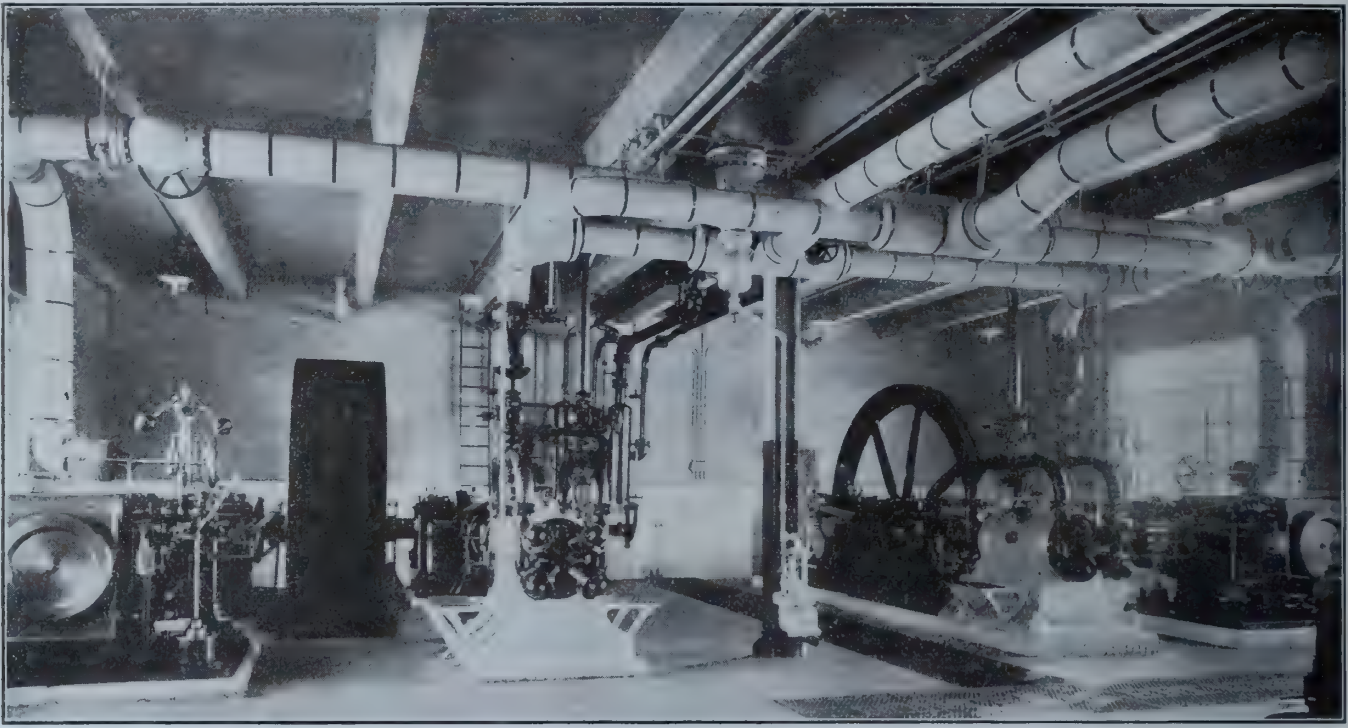
operation of the remaining coils. The condenser is of the flooded, counter-current type, the gas entering at the bottom and the liquid leaving at the extreme top. Condensing water is supplied by a motor-driven turbine pump, to be later described.

The main liquid ammonia receiver is located in the condenser room and is of the horizontal type, 20 inches in diameter by 16 feet long. It has the usual gauge glasses, valves, supports, etc., and connects with a smaller vertical receiver in the engine room. From the latter, the liquid lines run direct to the expansion coils.

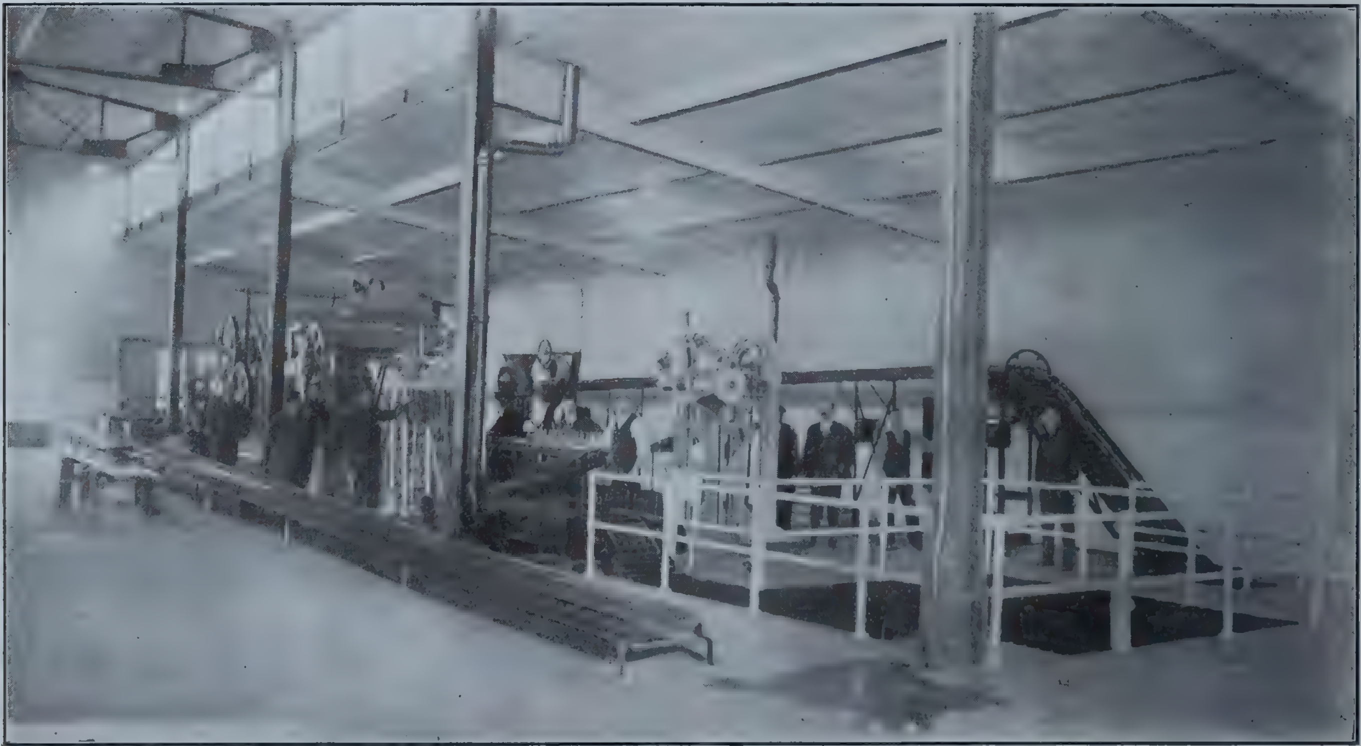
Power and Lighting Units.

For supplying current to the numerous motors throughout the brewery and for the lighting circuits, there are two direct-current units. Each consists of a 90- B.H.P. Belliss & Morcom quick-revolution compound engine, direct coupled to a 60 K.W. Canadian Westinghouse compound wound, 225-volt generator, running at 575 R.P.M. These engines were supplied under the following guarantee as to steam consumption, when using steam at 110 lbs. pressure with 90 degrees superheat and exhausting against 2 lbs. back pressure:—

At full load, 20.5 lbs. per B.H.P.
At ¾ load, 21.5 lbs. per B.H.P.



ENGINE-ROOM SHOWING THE VILTER AMMONIA COMPRESSORS.



INTERIOR OF BOTTLING DEPARTMENT.

At ½ load, 23.6 lbs. per B.H.P.

The engines are, of course, fitted with the Belliss & Morcom system of forced lubrication and also have that company's automatic expansion gear.

An artesian well, 500 feet deep, supplies most of the water used throughout the plant, and is operated by an air lift. For supplying air to the latter, there is a Belliss & Morcom vertical two-crank steam-driven air compressor, with compound steam and compound air cylinders. It has a capacity of 350 cubic feet of free air per minute compressed to 90 lbs. pressure, when running at 428 r.p.m. This compressor, in a shop test carried out by the builders, showed an overall efficiency of 4.9 cubic feet of free air compressed to 90 lbs. for each indicated horse-power developed by the steam cylinders.

Artificial lighting throughout the plant is by tungsten lights, the voltage in the 3-wire circuit being regulated by a 5-K.W. balancer set, built by the Eck Dynamo & Motor Co., Belleville, N.J.

The Switchboard.

As may be seen from the illustration, the switchboard presents a handsome appearance fully in keeping with the rest of the equipment. It was manufactured by the Northern Electric & Mfg. Co., Ltd., Montreal, and is of white marble with an ornamental electro bronze grille at top and bottom.

This switchboard differs from most in that part of the equipment is mounted on a panel at right angles to the main face of the board. This panel, which is clearly seen in the illustration, enables connection to be made with the lines of the Montreal Light, Heat and Power Company in the event of a breakdown. Of the four front panels the first one, that on the right, controls the current from the generators to the bus bars; the second controls the balancer set, while the third and fourth control the power and lighting circuits respectively. The equipment includes Weston voltmeters and ammeters, Duncan watt-hour meters for the power and lighting panels and a total load recording watt meter.

The latest types of high-grade switchboards are arranged so that no cables are exposed at the back of the panels. In most cases this is accomplished by mounting a steel pull box over the top of the board and extending the bus bars to a terminal board directly under the porcelain bushings mounted in the bottom of the pull box. It is usual to expose 12 inches of the cable as a maximum.

In the case of the switchboard under notice, the conditions were reversed and the pull box is mounted on the floor, the terminal boards being provided at the bottom of the panels instead of at the top. The generator and balancer cables extend about 12 inches from the pull box to their terminal boards, while the distance from the pull box to the feeder terminal is not more than 3 inches.

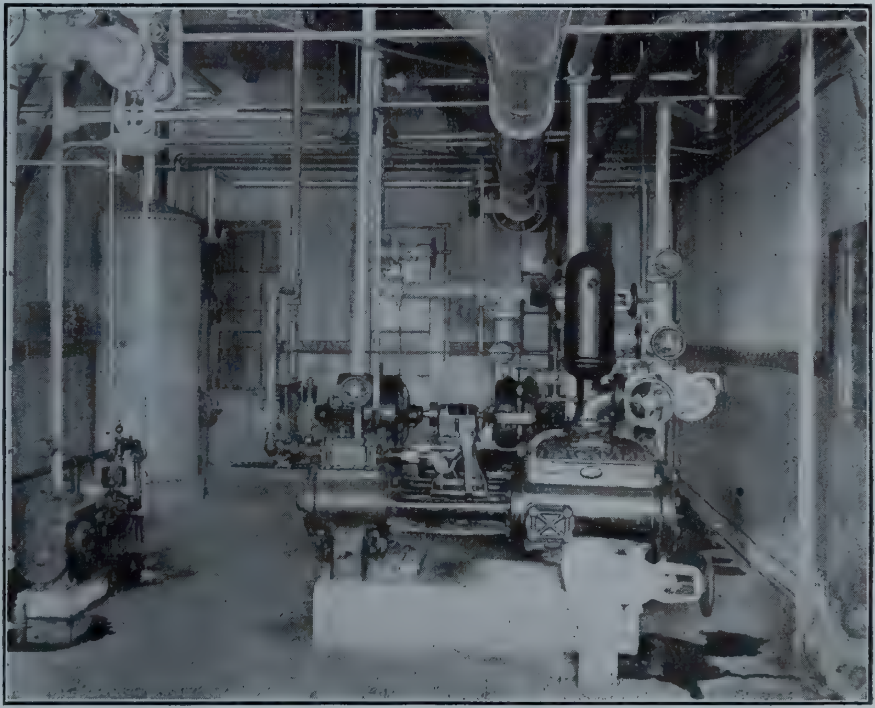
Another point of interest is found in the use of a marble cornice over the panels, and the sanitary slate base. Marble cornices have been used for a number of years; but the sanitary slate base has seldom been used in this country and the Frontenac Brewery probably possesses the first board on which this feature is to be found. It not only gives a pleasing appearance, but allows the floor to be thoroughly cleaned without filling the pull box with moisture. In the present case it raises the steel framework and the electro-bronze grille away from the floor and prevents damage from rust.

LOWER PART OF FILTER.

Pumps and Other Equipment.

At the lower end of the engine room there is a Clayton 8-in. x 8-in. single stage air compressor, operated through a short belt drive by a 10-h.p. Crocker-Wheeler motor. This compressor operates automatically, the motor being controlled by a Cutler-Hammer automatic starting panel. The output of the compressor passes through a Solar air purifier and is used for transferring beer between the different departments.

There is another Clayton compressor on the fourth floor of the brew house,



INTERIOR OF PUMP-ROOM.

outside the fermenting room. This is a two-stage, 8-4-8 machine, driven by a Link Belt Engineering Co. chain drive from a Sprague Electric Works 20-h.p. variable speed motor. The latter is controlled by a Cutler-Hammer automatic starting panel, fitted with two-speed regulation. This compressor draws the gas from the fermenters and compresses it to 250 lbs. for use in the racking room and bottling department.

Pump Room.

The water service pumps are located in a room at the north end of the engine room. As previously stated, the bulk of the water used in the plant is obtained from an artesian well, which supplies 300 gallons of water per minute at a temperature of 48 degrees Fah. The water is raised by an air lift into a concrete cistern below the pump house floor.

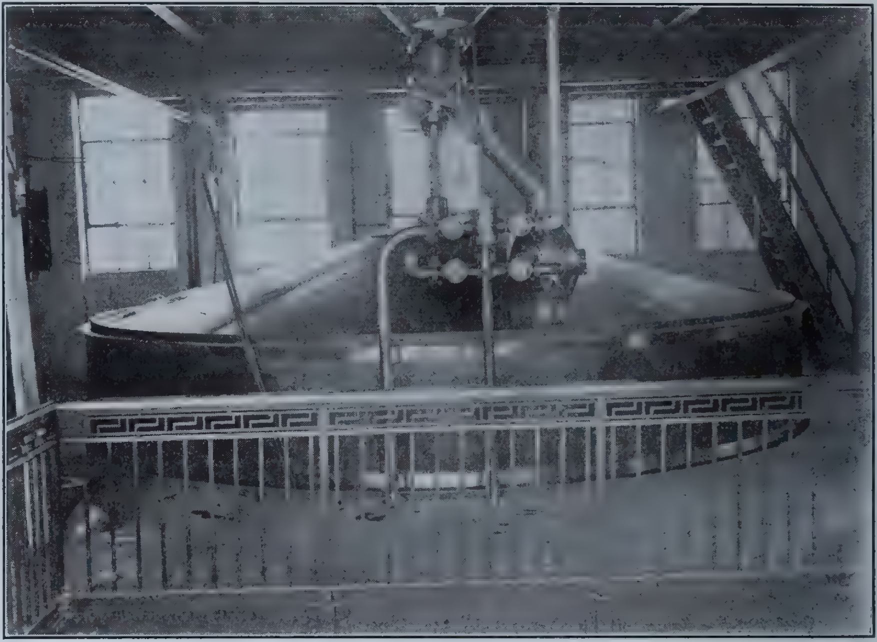
The general water service for the brewery is handled by a 300-gallon De Laval 2-stage turbine pump, direct-driven by a 25-h.p. Westinghouse compound wound motor. When this pump is not in use, water is supplied to the ammonia condensers by a 200-gallon single-stage De Laval turbine pump, direct-driven by a 4-h.p. Crocker-Wheeler shunt wound motor.

As a precaution against failure of the electric power, there is a 10-8½-10 Deane duplex steam pump. This is seen in the foreground of the illustration of the pump room. The turbine pumps are behind it, while on the left is seen the vacuum pump for dealing with the returns from the heating system, which was installed by the General Fire Extinguishing Company and operates on exhaust or live steam, as desired.

An underground concrete tunnel, 9 ft. high by 6 ft. wide, traverses the plant, and in this are carried all steam, exhaust, ammonia and water piping, together with the heating returns and lighting and power conduits.

Brewing Operations.

The product of this brewery is all lager beer of a high grade, made under the most modern and sanitary conditions. The building itself, as may be judged from the illustration, is an imposing structure. It is entirely of brick, steel and concrete, and is absolutely fireproof. The mill house in the centre of the building is five storeys in height and is topped by a cupola. The equipment in this portion of the plant includes a system of automatic conveyors which carry the malt from the receiving platform through a Richardson automatic scale supplied by Peacock Bros., Montreal, to the three malt bins, each of 5,000 bushels capacity, while another system of conveyors takes the ground malt from the mill into the brew house.

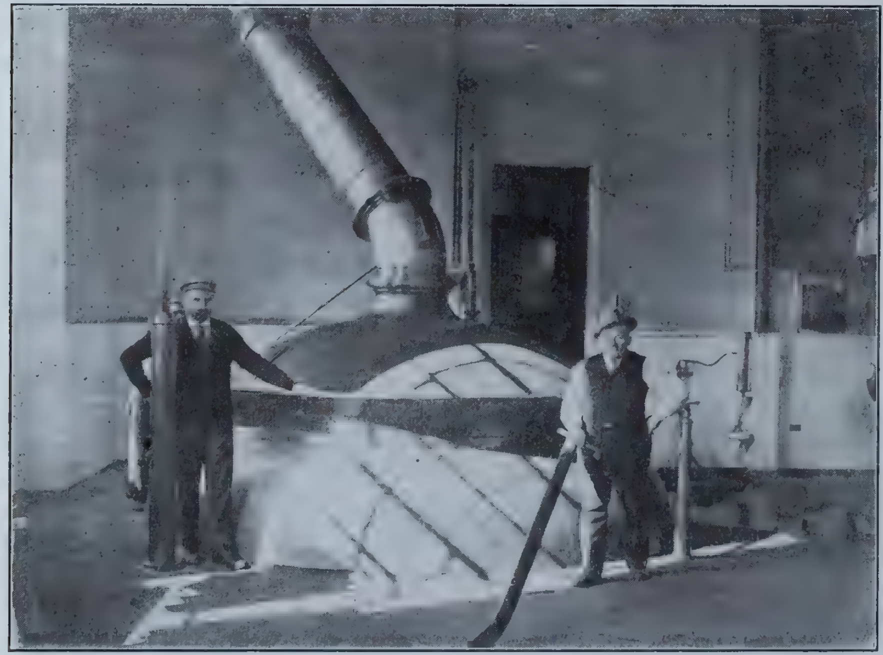


TOP OF MASH TUB.

In the latter building, there is the receiving hopper mounted on a Fairbanks hopper scale of 30,000 lbs. capacity. This is suspended over the mash tub which is 18 ft. in diameter and is operated by a 25-h.p. motor. On the floor below is the brew kettle, a copper vessel of 10,000 gallons capacity, the jacket of which is heated by live steam. The condensation is handled by a Bundy trap which returns it to the feed water heater.

On this floor too, there is the filter tub, 14 feet in diameter. Provision has been made for putting in a second kettle and filter, each of twice the capacity of those now in use. The kettle, mash tub, filter tub and two large hot water tanks in the brew house have all been lagged with 2 inches of 85 per cent. magnesia, finished with plastic cement and canvas, the work having been carried out by the Canadian Asbestos Co., Ltd.

On the bottom floor of the brew house is the hop jack, 16 feet in diameter, in which the hot wort is separated from the hops. From here the beer wort is pumped through two pipe coolers on its way to the fermenters by a 2-stage motor-driven centrifugal pump built by the Taber Pump Co., Buffalo. The motor is a 20-h.p. Crocker-Wheeler, direct-connected to the pump, and running at 2,000-2,500 r.p.m. Speed control on all variable speed motors throughout the plant is by means of field controlling rheostats.



VIEW IN BREW HOUSE, SHOWING UPPER PART OF KETTLE.

Of the two pipe coolers just mentioned, the first is a water cooler which brings the temperature of the beer wort down to that of the cooling water, and the second is an ammonia cooler in which the temperature is further reduced to that required in the fermenters—about 42 Fah.

In the fermenting room are twenty steel tanks of nearly 6,000 gallons capacity each. They are all glass enameled inside and electrically lighted. In them the beer remains during fermentation; the room being cooled by direct expansion piping.

From the fermenting room the beer passes to the storage rooms or cellars. There are two of these, each containing seventeen glass enamel-lined steel tanks of nearly 10,000 gallons capacity each. Space has been provided for twenty-four additional tanks of the same size. After remaining in these storage tanks until sufficiently aged, the beer is pumped through a filter on its way to the racking room and bottling department.

The style of keg used for draught beer is in keeping with the modern equipment everywhere in vogue throughout the plant. In place of the usual wooden barrels, galvanized steel kegs are used. These are glass enameled inside, and have a 1-inch cork lining between the steel shell and the glass enamel lining. In this way the contents of the keg are maintained at a low temperature during delivery, even on an all-day trip in the hot season. The glass lining, of course, makes the thorough cleansing of the keg an easy matter. This is done on a special keg-washing machine, an illustration of which is shown. The keg is rolled onto the cradle in front of the machine and its outside is first thoroughly scrubbed by revolving beneath the brushes. It next passes over a series of nozzles which inject a spray of high pressure water through the bung holes, thoroughly cleansing the glass enameled interiors.

The bottling department is of considerable interest, largely on account of up-to-date machinery having reduced manual labor to an absolute minimum. In the basement of this department is located the bottle-washing machine, which is served by three men only, yet can deal with nearly 6,500 bottles per hour. The cleaned bottles pass up to the bottling room by an elevator and are placed on a conveyor by one man. The conveyor passes them to the bottling and crowning machine, from whence they go to the Pasteurizer and labeling machines in the usual way. The capacity of this department is 108 bottles per minute or 6,480 bottles per hour when working at top speed. This gives an idea of the size of the Pasteurizer, through which it takes 90 minutes for the bottles to pass.

Insulation of Cellars, Etc.

The brewery cellars, fermenting room, etc., are all insulated with Nonpareil cork-board, the entire work having been carried out by the Kent Company, Ltd., Montreal. The walls all have a single 3-inch layer erected in cement and finished off with a ½-inch coat of Portland cement made with white sand to give a light appearance. In some rooms the ceilings are insulated with a single 3-inch layer of cork-board, while in others an additional 2-inch layer is put on, making 5 inches in all. The floor insulation is for the most part 4 inches thick and consists of two layers of 2-inch cork-board laid in hot asphalt.

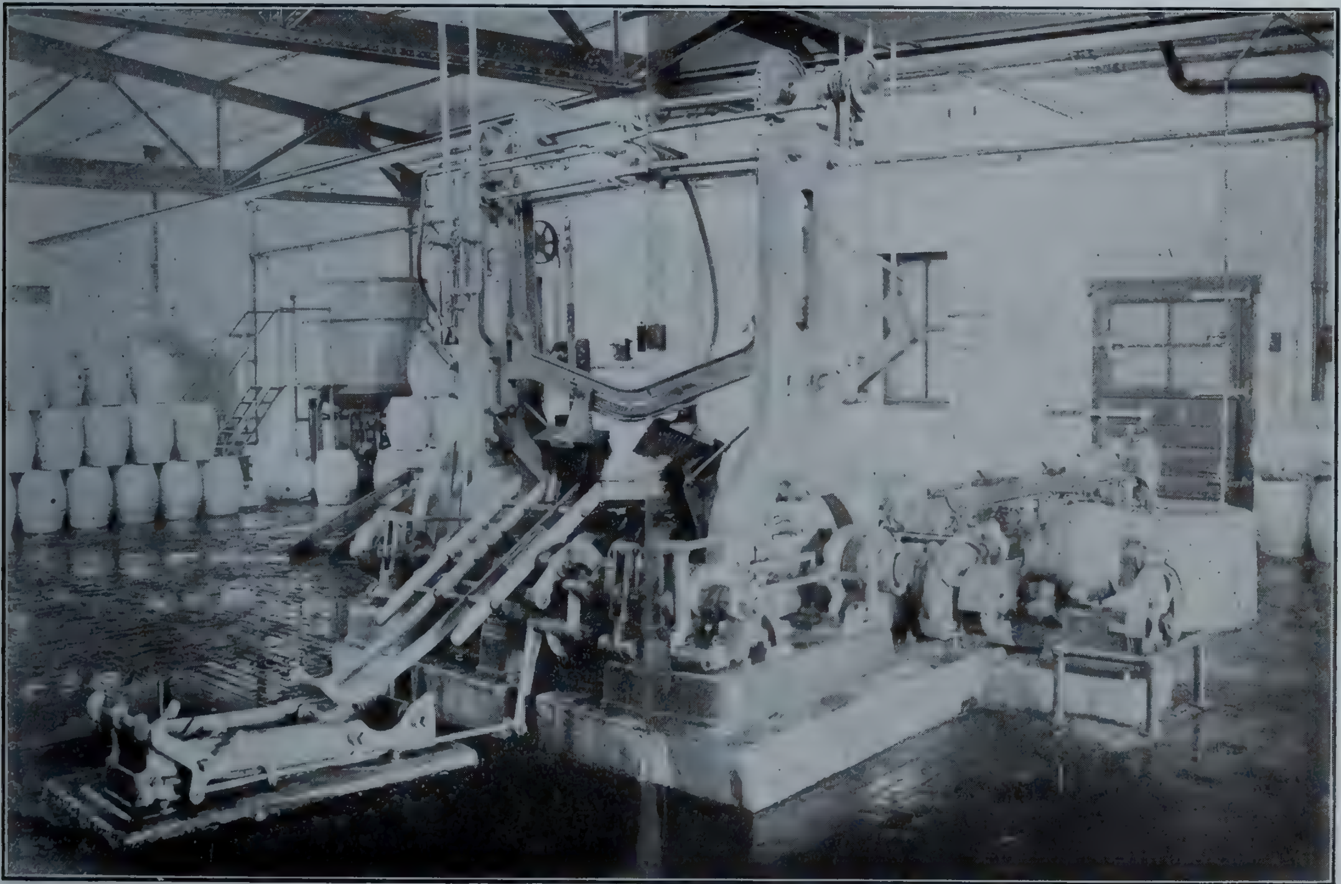
An interesting feature of this work is found in a number of partitions used to divide off some of the larger rooms. These cork-board partitions, 3 and 4 inches thick, are 24 feet high and are entirely self-supporting. They are believed to be the highest partitions of their kind ever built in Canada.

Direct Expansion Piping.

The brewery cellars are all cooled by direct expansion piping installed by the Vilter Mfg. Company. The volumes of the various rooms and the temperatures obtained are as follows:

First Floor.

Room	Cubic Feet	Deg. Fahr.
Filled keg storage	51,272	32
Racking room	16,996	32
Beer filter	5,815	32



KEG WASHING MACHINE, FRONTENAC BREWERY, MONTREAL.

Second Floor.		
Beer storage	60,700	34
Third Floor.		
Beer storage	66,484	34
Fourth Floor.		
Beer fermenting	85,100	38
Hop storage, etc.	45,365	32
Yeast room	690	32
Fifth Floor.		
Beer settling	17,890	38
Bottling House Basement.		
Bottling tank room	8,100	34
Total	358,406 cu.	feet.

The above rooms are refrigerated with a total of more than 21,000 lineal feet of 2-inch full-weight lap-welded ammonia piping divided into coils of suitable length, each coil being equipped with expansion and shut-off valves.

For cooling the attemporator tank, which is 10 ft. 6 in. diameter by 10 ft. high, there is a total of over 2,000 feet of 1¼-inch extra heavy galvanized ammonia piping made up into coils and supported on galvanized stands. All cold rooms throughout the plant are fitted with doors built by the Jones Cold Store Door Co., Hagerstown, Md.

This modern installation is understood to have shown remarkable economy in operation and is undoubtedly one of the finest examples of a refrigerating plant to be seen in the Dominion. Great pains have been taken to make everything conform to the latest brewery ideas, and all workmanship, material and design are in accordance with approved engineering practice.

Absorption Plant, Ritz-Carlton Hotel, Montreal

By H. L. Sackett *

This large hotel is equipped with a thoroughly modern absorption plant for taking care of the refrigeration and ice-making. The author points out the advantages of this type of installation, and describes the principles under which it operates. The plant has now been long enough in service to allow of an accurate judgment of its performance.

THE refrigeration plant at the Ritz-Carlton Hotel, Montreal, was installed by the Carbondale Machine Co., Carbondale, Pa., and consists of two 25-ton absorption machines, this capacity including 3½ tons of ice-making per day. The half-tones accompanying this article give an idea of the general appearance of the various units, while the line cut is introduced to enable the description of the operation of the plant to be more readily followed by those not already familiar with this system of refrigeration.

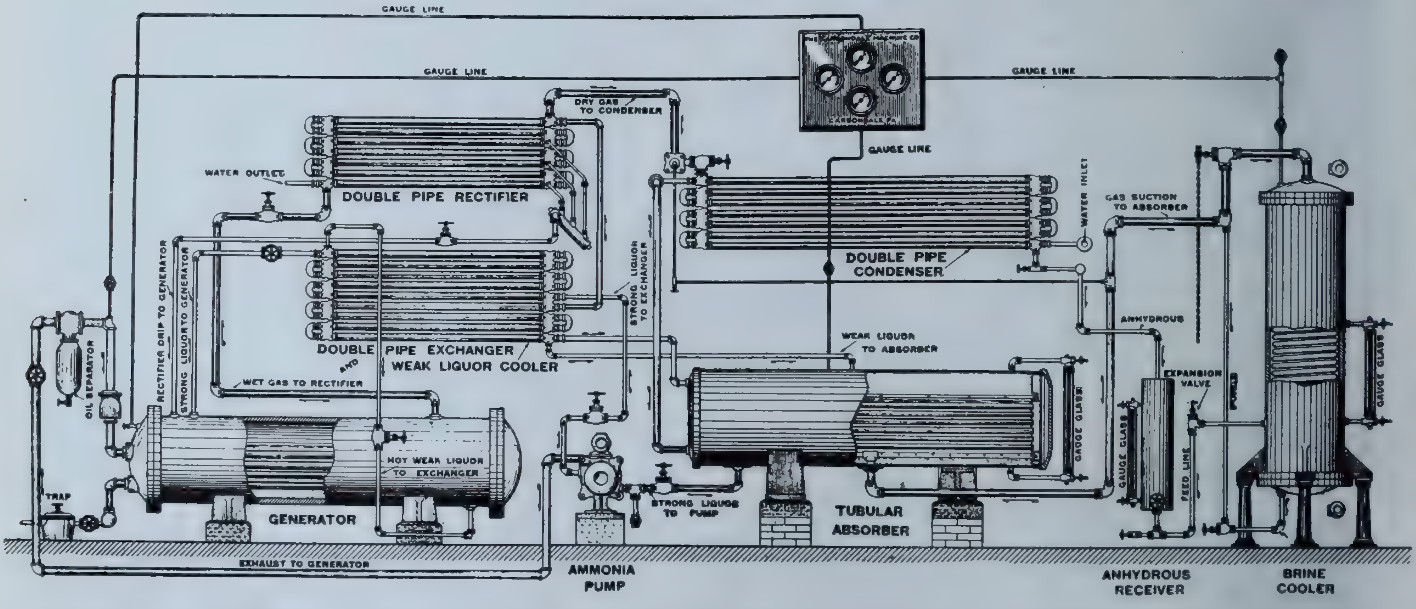


DIAGRAM OF ABSORPTION REFRIGERATING MACHINE AS INSTALLED IN THE RITZ-CARLTON HOTEL, MONTREAL.

Some of the advantages of the system may be stated as follows:—

There is practically an entire absence of moving parts and of consequent noise and vibration, since there is no compressor or steam engine. A small steam pump to deliver the ammonia liquid back to the generator is the only moving part.

In case of break-down repairs are very readily effected.

There is a great reduction in the quantity of engine room stores that have to be carried.

The steam consumption of the generators is very low.

Great economy may be effected by using the exhaust steam from the ammonia and brine pumps in the generator, using live steam to supplement it when the circulating water reaches a high temperature.

RITZ-CARLTON HOTEL.

The water consumption is low, as the same water passes through all four parts of the machine in rotation. It first enters the bottom of the condenser, from whence it passes to the absorber. It next goes to the weak liquor cooler and thence to the rectifier. During the passage of the water through the machine it has picked up several degrees of heat, which are utilized by discharging the bulk of the water into one of the hot water heaters used in connection with the hotel water service. The remainder of the water passes through a spring-loaded valve into the main suction tank to be used again for general purposes.

---

*Chief Engineer, Ritz-Carlton Hotel, Montreal.

When the machine is in operation there are three distinct circulations going on simultaneously. Consider first the ammonia circuit.

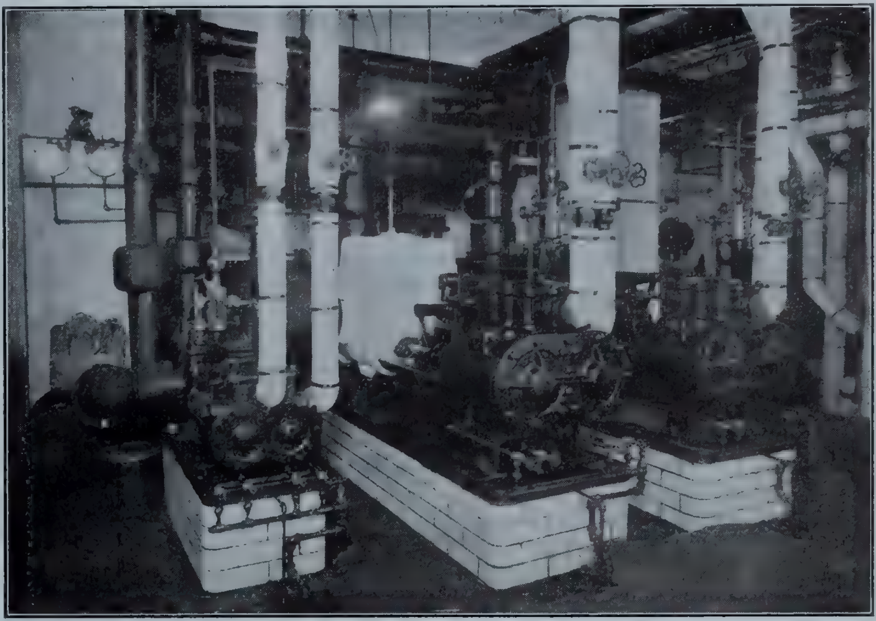
Ammonia Circuit.

The heat of the steam in the generator coils drives off ammonia gas from the ammonia liquor, which, together with a certain proportion of moisture, rises into the rectifier seen in the illustration directly above the generator. In the rectifier, the moist ammonia gas is partially cooled, the moisture being condensed and returned to the generator.

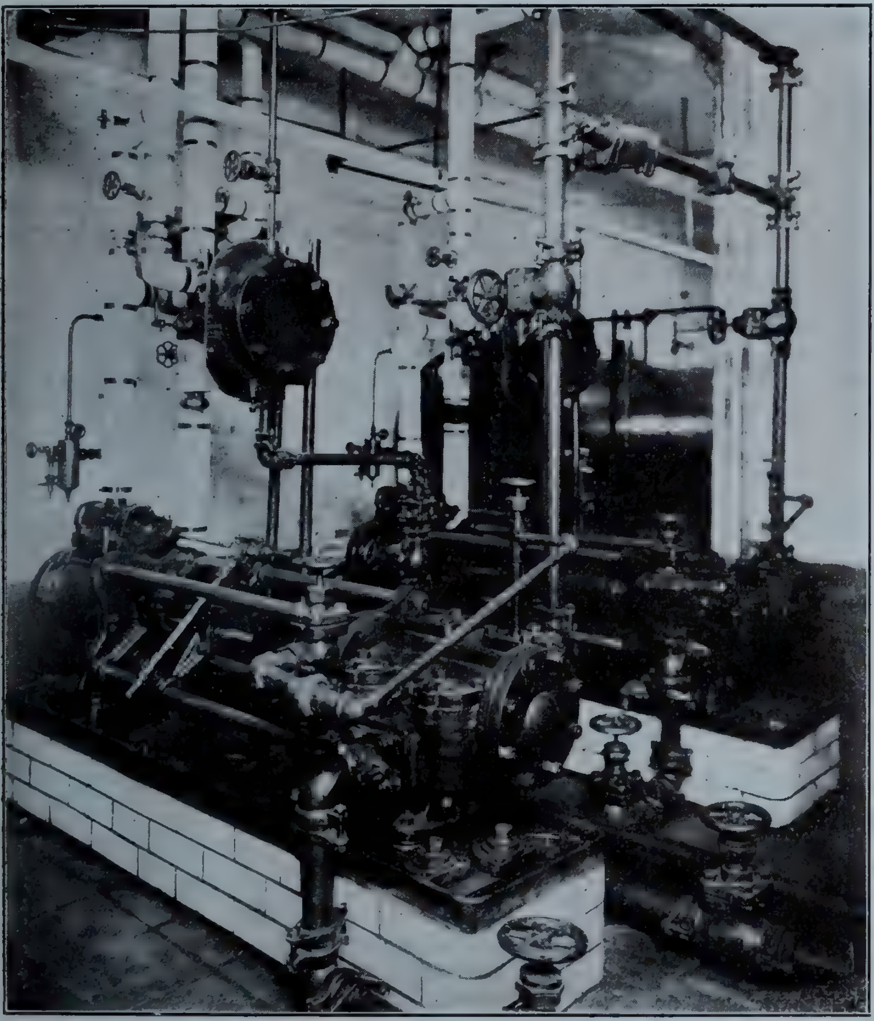
The partially cooled gas, free from moisture, then passes to the condenser where it is further cooled and liqufied after which stage it is known as liquid anhydrous ammonia. From the condenser, the liquid passes through the expansion valve into the cooler where it evaporates, producing a very low temperature. It is now, of course, in the form of gas and returns from the cooler coils into the absorber.

Weak Liquor Circuit.

The liquid left behind in the generator after the ammonia has been driven off, is the weak liquor. This passes out of the generator into a double pipe heat exchanger, where it is cooled, and then into the absorber. Here it meets and absorbs the ammonia gas coming in from the cooler.



BRINE CIRCULATING PUMPS.



AMMONIA CIRCULATING PUMPS.

Strong Liquor Circuit.

The combination of weak liquor and ammonia in the absorber is called the strong liquor. This liquor passes from the absorber when the latter is about three parts full, into the suction pipe of the ammonia pump. It is then pumped through the inner tubes of the exchanger, receiving heat from the weak liquor passing on the outside of the tubes. From the exchanger, the liquor is delivered into the generator, where the ammonia gas is once more driven off, the weak liquor settling to the bottom. The circuit is thus completed. The ammonia pump is fitted with an automatic float and valve which controls the flow to the ammonia pump according to the height of strong liquor in the absorber.

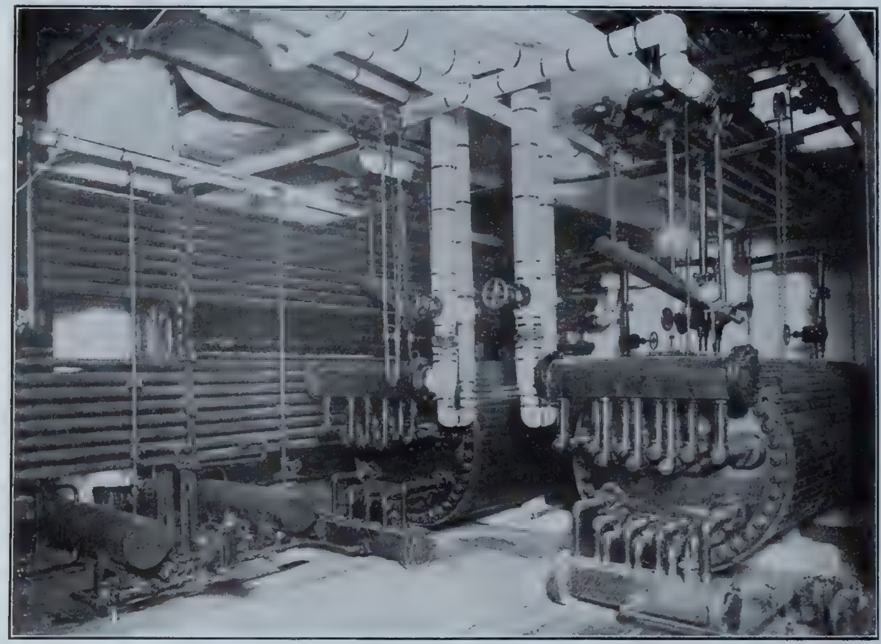
Ice-Making Plant.

The ice-making plant consists of a brine tank 14 ft. long, 8 ft. 9 in. wide and 4 ft. deep. In this, 72 cans are suspended, each containing 150 lbs. of distilled water, obtained from a single Carbondale evaporator. The return pipes of the brine system are conveniently arranged so that the circulation of brine in the tank can be increased or decreased according to the amount of ice required.

The Brine Circulating System.

The brine system consists of three Deane duplex pumps supplying a high pressure and a low pressure line. The high pressure line supplies brine to one cold storage box on each floor of the hotel, which is twelve storeys high. The low pressure line supplies all cold storage rooms and boxes in the wine cellar, kitchen, stores and bars.

During the summer months of last year, the circulating water often reached a temperature of 78 degrees Fah. and the consumption of ice was steady at 3.3 tons per day for 35 days. Notwithstanding this, one unit proved itself capable of handling the situation with ease, the other merely forming a stand-by.



GENERATORS, RECTIFIERS AND AMMONIA CONDENSERS.

◆

PRE-COOLING PLANT AT GRIMSBY, ONT.

THERE is being built at Grimsby, Ont., a pre-cooling plant for the Department of Agriculture, Ottawa, for cooling strawberries, peaches and similar fruits prepatory to shipment when destined for distant points. The fruit growers in the Grimsby District have been under a disadvantage when shipping fruit to long distances, such as the western markets, on account of the inadequate facilities for cooling it in a satisfactory manner during transit. The liability of the fruit being spoilt on account of the heat is great. The ordinary refrigerator car is not entirely suitable for transportation, as the heat should be extracted from the fruit before shipment. In the pre-cooling plant, however, the fruit will be thoroughly cooled before shipment and so will be kept in better condition during transit.

The building is being erected to the designs of Mr. E. J. Greenstreet, F.R.A.I.C., refrigerating engineer, Toronto, and the mechanical equipment is being made and installed by the Madison Cooper Co., Calcium, N.Y., who make a specialty of this type of plant. The building is of frame construction, two storeys and basement, and an ice house at the back extending the full width and height of the structure. A railway siding runs along one face of the building, and a shipping platform along the opposite side. The cooling plant will be on the gravity brine system. The basement will be used for the storage of fruit with a receiving and handling room in the front section. There will also be an experimental plant consisting of a coil room and a pre-cooling room, with a primary tank on the second floor. This plant will be precisely of the same type as the main plant, but independent of it and of smaller dimensions. On the main floor will be four pre-cooling rooms having a total content of 20,000 cub. ft.; also the shipping room and office.

Above the pre-cooling rooms will be the two coil rooms equipped with the requisite number of coils composed of wrought iron pipe through which circulates the calcium chloride or brine solution. Adjoining the coil rooms will be the fans and storage for cases. In the roof above the coil rooms there will be five primary tanks containing a series of coils connected with those in the coil rooms. In the tanks and around the coils a mixture of crushed ice and salt will be deposited, the proportion of salt being varied according to the temperature required in the pre-cooling rooms. Above the roof is a tower to the top of which crusher on the ground floor in the ice crusher on the ground floor in the ice house by means of a bucket elevator operated by a 3 h.p. motor. The crushed ice is delivered from the tower to the primary tanks by means of spouts. There will be a freight elevator installed by the Otis-Fensom Co., of 2,000 pound capacity for handling the fruit, etc.

In operation, the calcium chloride in the coils is cooled in the primary tanks and flows down through the coils in the coil rooms reducing the temperature of the air in these rooms. The cooled air is forced through the coil rooms by two 60-inch fans each driven by a 3 h.p. motor at 300 r. p. m., and delivered through ducts to the pre-cooling rooms. The ducts are so arranged that all the cool air can be delivered to any single room or distributed to all the rooms. The air is delivered to the underside of the false floor and rises through gratings, cooling the fruit, and is drawn off through gratings in the false ceiling to the ducts and re-circulated. The walls of the coil and pre-cooling rooms are insulated with waterproofed paper and mill shavings. On the coil room floor will be installed a 60-inch fan for ventilating the coil and pre-cooling rooms when required.

The ice house will be approximately 45 x 30 x 37 ft. high, and will have a storage capacity of about 1,200 tons of ice. There will be a bucket elevator installed for handling the crushed ice. The fans, ice crusher and other equipment are specially designed for this class of work by the Madison Cooper Co. The plant will be in operation by the beginning of the coming season, and the results will be watched with interest, for, if it be as successful as is anticipated, other plants will no doubt be built at other fruit growing centres.

◆

Brantford, Ont.—The Brantford Ice Co. will shortly build a new plant, and manufacture artificial ice.

Galt, Ont.—The town council has before it a proposition to install a municipal ice-making plant in connection with the waterworks system. They discussed a communication from a Montreal firm of ice-making machinery manufacturers.

Regina, Sask.—A number of prominent business men, with the backing of the Regina Board of Trade, are advocating the establishment of a municipal abattoir, with which may be connected a storage plant, curing house for hides, tannery, etc.

Edmonton, Alta.—The Triumph Ice Machine Co., Cincinnati, have just secured the contract for the refrigeration plant at the McDonald Hotel of the Grand Trunk Pacific Railway. The principal equipment will consist of two 20-ton steam-driven ammonia compressors.

The Refrigeration Plant at Bonsecours Market, Montreal

By Charles Bishop *

This Municipal Market is the only one in the Dominion provided with mechanical refrigeration, although others are about to be so equipped at Maisonneuve, Que., and Edmonton, Alta. The installation here described was put in without in any way interfering with the usual business of the market. There are between seventy and eighty stall-holders, about forty of whom are supplied with refrigeration from this plant.

SOME years back, a proposal was considered to fit a central refrigerating plant, from which the numerous tenants of the Bonsecours Market, Montreal, could secure cooling effect for their refrigerator rooms and boxes and so avoid the use of ice, which was more or less unsatisfactory as to supply, temperatures secured, trouble of loading the ice boxes which interfered with the public and tenants, and also on account of the unsanitary results secured. The City Council last year instructed the writer to prepare plans, specifications and estimates for a suitable complete refrigerating plant, and to report upon the operating expenses and name the necessary charge to the various tenants to meet the investment and overhead charges. This report was carefully considered and investigated by the city engineers and as a result the writer was instructed by the city to act as their engineer and have the plant installed.

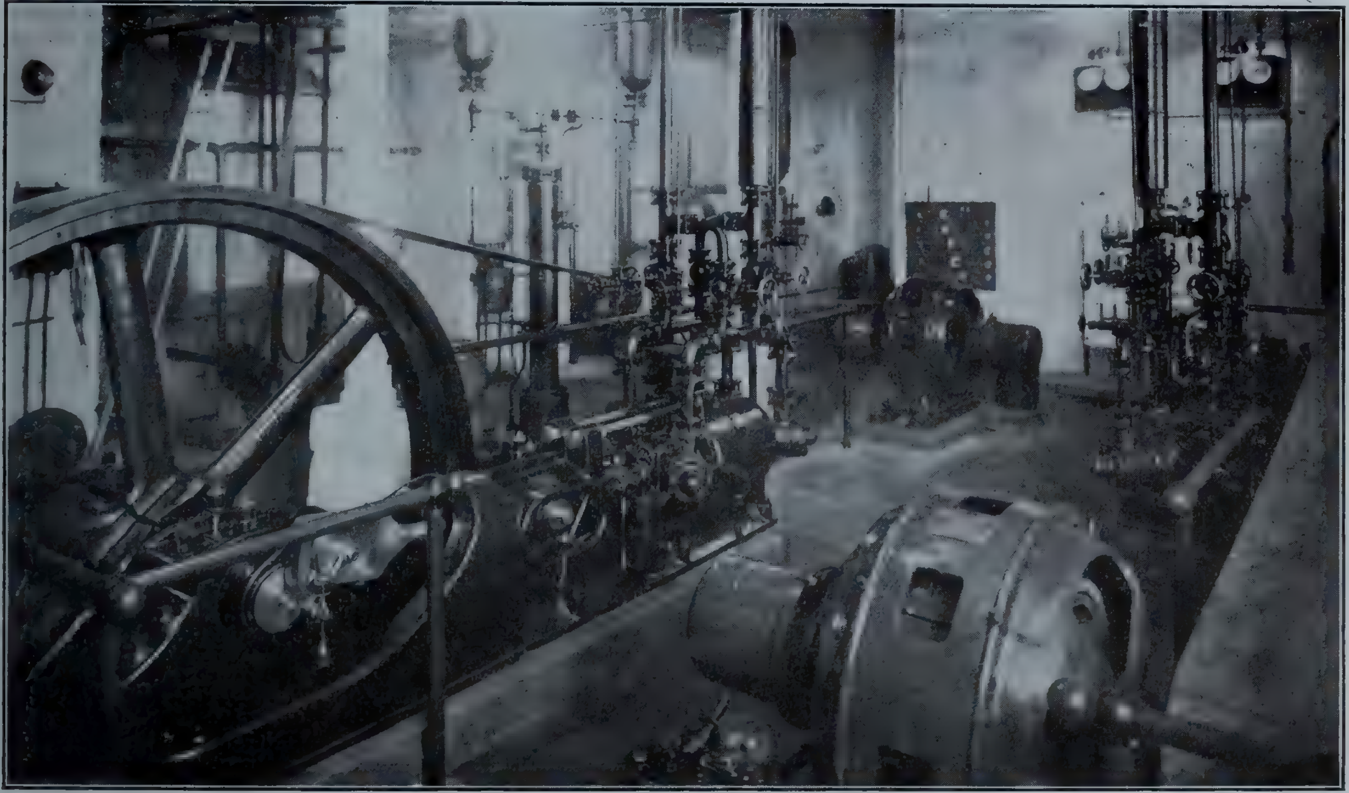
Features of the Installation.

In several details the plant is novel, as it had to be specially designed to suit very unusual conditions. In the first place, the various refrigerator rooms and boxes were existing, and had to be kept in operation for business whilst the erection of the refrigerating plant was proceeded with. The city water supply is very unreliable, being intermittent, and furthermore very expensive; the water-department charging the market department as an ordinary outside customer. Therefore, not only was water economy essential, but provision had to be made to avoid trouble from a possible shut-down of the supply for about 48 hours at any time.

Then again, by agreement with the tenants, a guaranteed temperature was offered which should not vary more than 2½ degrees Fahr. above and below the stipulated temperature. Furthermore, while there are about 40 separate tenants taking refrigeration, the supply of cooling agent was to be under individual control, yet at the same time in the hands of the engineer of the central plant. The great bulk of the work is done upon fresh meat, so that it was necessary that every cooling chamber should have full and good dry air circulation in order to obtain the best results.

As the agreement with the tenants stipulated that every precaution would be taken to safeguard against breakdown, the whole plant is in duplicate even down to the point of having two separate main power lines running to the switch-board from distinct and separate mains; so that in event of failure of one, the other source is tapped by changing over the main switch, which can be done in a few minutes. In addition to this duplication, the two plants are in all main points cross-connected, so that several main items can be cut out at will. The brine pumps are of special design to deal with the varying pressure set up by a number of tenants shutting off or opening up the brine service simultaneously. It is interesting to note that the estimates prepared many months previous to the tenders being submitted were very close. The Canadian contractors' prices were all within about 5 per cent. of the original estimates.

The plant has been in service since



TWO 50-TON YORK AMMONIA COMPRESSORS.

---

*Consulting and Refrigeration Engineer, Montreal.

April 1913, and has been an unqualified success, having given full satisfaction to all concerned. During the heat wave of last summer, the one plant was capable of taking care of the maximum requirements, without any call being made upon the stand-by. Also, upon occasion, the city water supply was cut off for periods of from 24 to 48 hours, without in any manner interfering with the proper working of the plant.

The butchers' display refrigerators are on the St. Paul street level, and average about 18 ft. x 10 ft. x 9 ft. high inside with a space above, about 5 ft. high, containing the brine coils. There are also a large number of cold rooms and refrigerator chambers, as well as boxes used for butter, cheese, eggs and poultry upon the cellar level—about 10 feet below the St. Paul street level. The machinery is about 19 feet below the market floor level and the engine room opens upon Commissioners street.

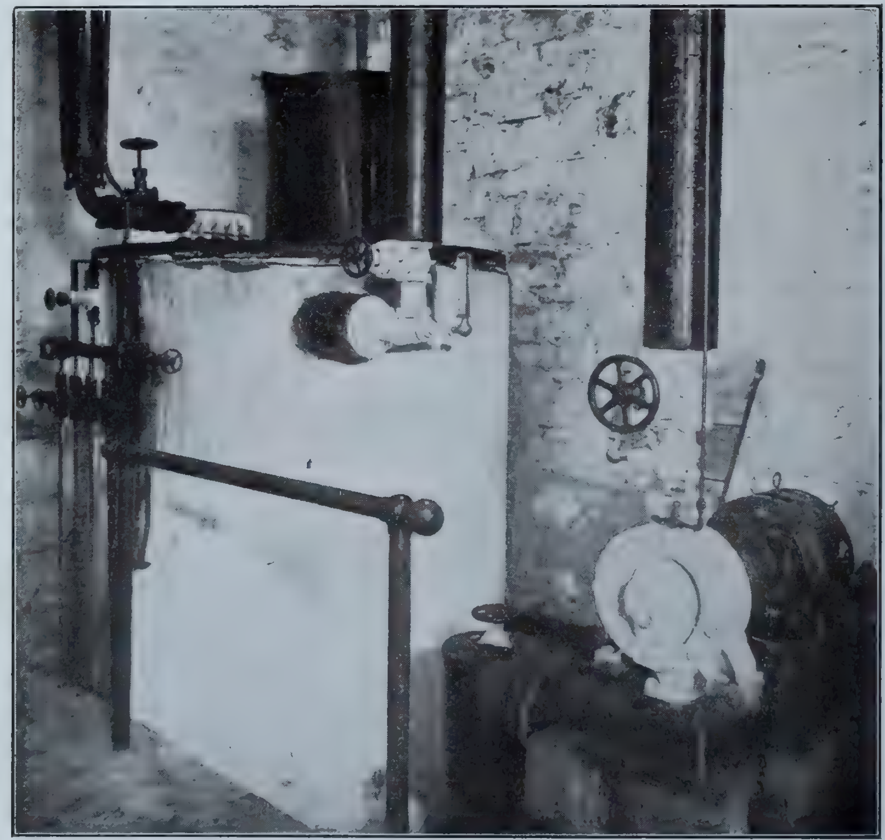
The Ammonia Compressors, Etc.

The complete contract for the refrigeration plant was awarded to the Kent Co., Ltd., Montreal. There are two horizontal double-acting York ammonia compressors, each of 30 tons refrigeration capacity at a speed of 75 r.p.m. They have heavy pulleys 10 ft. diameter by 15-inch face, taking a 14-inch belt drive direct from an electric motor. The compressor runs "in," bringing the slack side of belt on the top, without any really unnecessary jockey or tension pulleys, and with 25-ft. centres this endless leather belt drive is one of the sweetest possible. In fact one has to watch closely to make sure the belt is really running. The compressors are water-jacketed and fitted with removable liners pressed into the housing. They have solid pistons with Ramsbottom rings.

Each compressor is driven by a slip-ring induction motor taking current supplied by the Montreal Light, Heat and Power Co. Current is 550 volts, 3-phase alternating, 60 cycles. The motors are of 60 h.p. at 460 r.p.m. full load speed, but are not loaded nearly to their limit, the maximum being from 48 to 52 h.p. under full load summer conditions. Each motor has an oil-resistance starter close to the machine with a trigger release; and as the compressors have full size bye-pass and pump over connections, the starting duty upon the slip-ring motors is extremely easy. The motors were supplied by Bruce Peebles & Co., Edinburgh, Scotland.

The Condensers.

The engine room space has two recesses, each about 26 feet long by 7 ft. 6 in. wide. These are utilized for the ammonia condensers which are upon the surface evaporative system. Each condenser has four stacks of 2-inch pipes, 20 feet long by 24 pipes high, and each has a liquid ammonia receiver, 20 feet diameter by 7 feet long. The condensers are carried upon steel joists over a reinforced concrete tank 23 ft. x 6 ft., 6 in. x 6 ft. depth of water.



ONE OF THE BRINE CIRCULATING PUMPS AND BRINE TANKS.

The water over the ammonia condenser is caught in the tank and sent back in circulation by a 3-inch brass-fitted centrifugal pump. The condenser compartment is sealed and fitted with suction and delivery air ducts, and the air in the engine room is drawn by a 48-inch propeller type fan, forced over the condenser, discharged through ducts and delivered into St. Paul street at a height of about 25 feet above the sidewalk. This air circulation can be produced over either or both of the condensers together, and the same arrangement applies to the water circulating pump.

Both fan and pump are belted from a 6 h.p. Bruce Peebles motor taking 550-volt current. The water actually consumed is only that required to replace the quantity evaporated by the air current, and upon test the quantity contained in the concrete tank has been found sufficient to allow for a run of 48 hours, as before stated.

The average quantity consumed per hour for the 30-ton plant is about 280 gallons at 65 degrees Fahr., and this is let into the distributing troughs above the condenser. To provide against breaking down of the circulating pump and fan, the town water make-up pipe is large enough to give full normal quantity in case the surface evaporative system is not needed, as in winter time when the working hours are greatly reduced.

Brine Coolers and Pumps.

The brine pumps are each capable of pumping 7,980 Imperial gallons of calcium chloride brine per hour against a pressure varying from 18 to 22 lbs. per square inch, the weight of solution being 12½ lbs., per Imp. gallon. These pumps are "Rees Roturbo" patent make and, by the way, must not be confused with the ordinary turbine type of pump. The pumps are each direct-connected to a 6-h.p. Bruce Peebles motor running at 1,800 r.p.m., and under maximum conditions take about 5½ h.p. As the roturbo pump automatically adapts itself to varying conditions of head, no relief or bye-pass valve is required. In other words, the driving power remains practically a fixed quantity at a fixed speed, variation of pressure merely reducing or increasing the quantity of brine delivered. It was this very novel feature that led to their adoption for the work and they have proved exceedingly satisfactory under the hard conditions of pumping a heavy solution of calcium chloride at a temperature down to three degrees Fahr. against a fluctuating delivery head. In fact all tenants can shut off the brine supply simultaneously without any injurious effect upon the pump or its motor. The coupling has a floating connection, special insulating ferrules being also fitted around the flange studs to prevent the low temperature of the pump spindle causing condensation upon the rotor.

STALL OF GUNN'S, LTD., BONSECOURS MARKET.

These pumps are cross-connected to the two evaporators or brine coolers so that one pump can, if required, work upon both brine coolers. These brine coolers are of the submerged type and consist of steel cylindrical tanks 6 ft. 6 in. diameter by 9 ft. deep, each containing 2,250 feet of 1¼-inch continuous extra heavy welded piping arranged in five coils of equal length. The liquid is bottom fed and in order to simplify the replacing of any one coil, the bottom coil ends are passed straight through the tank bottom and made water-tight by a special split stuffing box. There is no mechanical agitator, but, by an ingenious and simple contrivance, the brine flow is utilized to give the desired effect and this method has proved a great success.

The brine coolers are thoroughly insulated with a double thickness of Nonpareil cork lagging put up in asphalt, properly banded and finally covered with about ½ inch of Portland cement plaster, neatly painted.

The Brine Mains.

The brine mains are located below the main market floor and are run upon the ring system, with lengths of heavy piping having flanged ends where necessary. They are properly insulated with heavy Nonpareil cork sectional lagging. From the mains a feed and return lead is run to each refrigerator box; or, in the case of the larger rooms fitted with several systems of piping, a lead is run to each system. These feed and return leads have each two valves, one being a master valve which is operated through a sunk fitting in the public passage of the market floor and which can only be operated by a special key possessed by the city engineer. The other valve is situated within the cold room and can only be operated by the tenant. In this manner the requisite amount of refrigerated brine necessary for each individual tenant's duty has been ascertained, and the master valve is so set. By means of the second valve the temperature can be raised if necessary by the tenant to suit his special needs or lowered to the agreed minimum, if he so desires.

The brine pipes for the butchers are placed in overhead bunker lofts originally used for the ice, and the systems of piping have been so arranged as to give the best possible amount of air circulation in the rooms below. All piping is very heavy 2-inch tubing heavily galvanized and carried on galvanized iron supports and bearers, all valves being solid brass full way type. Each system of piping is provided with the necessary pet cocks to prevent air locks.

As all the butchers' premises are above the machine room the feed mains are fitted with check valves and the return mains are provided with atmospheric stand pipes to prevent the brine leaving the brine system during any stoppage of the plant. Since the brine pumps are combined with separate motors the brine may be brought down in both brine coolers if necessary and after the refrigerating machinery is stopped, the circulating brine pump may be run alone. This flexibility helps considerably to ensure satisfactory results. For instance, in the heat of summer, during the night watch, when the market is closed and the meat, heated by the day's display, is sealed up, by reason of the cooler night hours and the sealed doors the machine gets control of the duty and brings the brine well down. With the "Roturbo" brine pump the engineer can then reduce his brine delivery, keeping pace with the work taken up and packing away the surplus negative heat in the brine coolers. When the busy market day opens, the surplus can be utilized by opening up the brine delivery, thus helping to maintain the uniform temperatures insisted upon by the tenants. The temperatures of the brine feed and return are indicated by thermometers within the engine room. The ammonia system is fitted with a Vilter regenerator and oil separator which gives full satisfaction and effectively removes all oil, etc., from the system.

In view of the rather severe comments made recently as to the backward and unsatisfactory state of Montreal's municipal affairs, it is only fair to point out that this refrigerating plant at their principal city market, after a year's hard test is a real evidence of most progressive improvement and a somewhat difficult job brought to a very satisfactory conclusion, and as the plant has proved itself against the most trying conditions and has satisfied the users, it may safely be listed as one of the good works carried out last year by the city authorities.

* * *

HOTEL REFRIGERATION AND ICE PLANT.

ALTHOUGH a refrigerating plant is recognized as part of the equipment of any new large hotel, still not all managers of hotels, using the old system of iced boxes, appreciate what a paying investment a mechanical plant can prove in their own place. The plant recently installed in the Prince George Hotel, Toronto, is a good example of a medium sized outfit, doing most successful work.

It consists of a 7½ in. x 7½ in. "York" two cylinder, vertical, single acting enclosed "Automobile" type ammonia compressor, direct connected to a vertical silde valve engine. The ammonia condenser is of the double pipe type made of 2 in. and 3 in. pipe, which is larger than standard, to allow of the water supply to the hotel from the city mains to be first by-passed through this condenser. As more water is used in the hotel for the closets, kitchen, baths, etc., than is required for the ice machine, there can be no charge made against the latter for water.

The combined brine storage and freezing tank is 13 ft. x 8 ft. x 38 inches, with bulkhead down the middle so that a higher temperature can be carried in ice freezing compartment is arranged for in which the brine coolers are located, thereby getting better quality ice. The ice freezing compartment is arranged for freezing 3,000 pounds of ice per day, part in fifty-pound moulds, and the rest in one hundred pound moulds. The ice is used for table, packing ice cream, the bar, etc. A 7⅝ x 8 x 9 Burnham steam pump is used for circulating the cold calcium brine from the tank through coolers to refrigerators and return, and there is also an auxiliary pump of the Worthington duplex type for use in case of break-down.

AMMONIA COMPRESSOR AND CONDENSER.

Both the compressor engine and pump exhaust into the hotel heating system in winter, and, in summer, this exhaust will be utilized for heating water for kitchen and hotel purposes. Accordingly, the charge against the plant for power is only nominal, because live steam has to be used in addition to this exhaust from compressor engine and pump to make up the necessary amount required for heating this water and for kitchen purposes.

BRINE TANK AND PUMPS.

A recording thermometer for brine temperature, socket thermometers, ammonia and steam gauges, give every facility for operating the plant at maximum efficiency. "Nonpareil" pure cork sheets are used for insulating the brine tank, and the same make moulded pipe covering is used for the brine and ammonia suction mains.

Besides making 3,000 pounds of ice per day, mentioned above, the plant cools by means of brine circulating coils, the following:—

Steward's Box, 16 ft. x 7 ft. x 7 ft. Temperature 34 deg.

Baker's Box, 11 ft. x 4 ft. 6 ins. x 7 ft. Temperature 40 deg.

Grill Room Pantry Box, 5 ft. 6 in. x 3 ft. 6 ins. x 6 ft. Temperature 35 deg.

Butcher's Box, 21 ft. x 6 ft. x 6 ft. 6 ins. Temperature 32 deg.

Back Bar, 30 ft. x 2 ft. x 3 ft.

All these boxes which were formerly cooled with salt and ice did not have to be altered to accommodate the new system. The saving obtained with the mechanical plant, if only the cost of ice, salt and labor is considered, is at least 80 per cent. of the first cost of plant per year.

The plant complete was furnished and installed by the Canadian Ice Machine Co., Ltd., of Toronto, and was in operation six weeks after receiving the order.

INTERESTING COLD STORAGE PLANT.

ONE of the principal features of the Wm. Davies, Ltd., Toronto, packing plant is the cold storage facilities.

The main building is 96 ft. x 65 ft., and consists of five floors, each having 55,000 cubic feet capacity of cold storage space. Each floor, again, is divided into three rooms, making a total of 15. These are used as freezers, having temperatures ranging from zero to 15 degrees, sharp freezers from zero to 10 below, and coolers from 30 to 45 degrees. The outside walls have 4-inch sheet cork, finished with a cement plaster coat. The partitions are made up entirely of 4-inch cork, and the ceilings have 2-inch cork. The roof is insulated with 5-inch cork sheeting, upon which is laid 2-ply "R. & T." felt and 3-ply "Salamander" roofing. On the floor of the basement are laid cork sheets 6-inch thick.

In another building are six hog chilling rooms with a total cubic capacity of 114,360 feet. The walls and floor are insulated with 4-inch sheet cork, while partitions are made of 4-inch cork, with cement plaster coat on each side. The roof is the same thickness and construction as the cold storage building already described. The chill rooms are equipped with a number of overhead runways for carrying hogs into the cutting-room adjoining. On the floor below the chill rooms are two freezers for general produce, maintained at a temperature of from zero to 5 degrees above, and having a total capacity of 127,800 cubic feet. The insulation consists of 4-inch cork sheets on the walls, 4-inch cork partitions, and ceilings of 3-inch cork sheeting. Adjoining the freezers is a storage room having a cubic capacity of 6,600 ft., and which is maintained at a temperature of 40 degrees Fahr. The walls and ceiling are insulated with 3-inch cork sheeting, and 4-inch material is laid on the floor. All the rooms are equipped with brine circulating pipes, the cooling being effected on the ammonia absorption system. The insulation was supplied and installed by the Canadian H. W. Johns-Manville Co., Ltd., Toronto.

Refrigeration Equipment, Etc., Wm. Neilson, Ltd., Toronto

Staff Article

It is perhaps not generally realized that the refrigeration machinery and accessory apparatus necessary for the production of that highly appreciated and much-in-request delicacy, ice cream, fill such a large and important place in the sphere of its manufacture. A perusal of the data here given, covering a large modern and exclusive factory, will be at once convincing and instructive.

THE consumption of ice cream is increasing yearly, and every company doing a large business in this commodity requires a refrigerating plant of considerable size to take care of the demand, especially during the summer months. Hygienic considerations call for care and cleanliness in manufacture, and these conditions exist to a high degree at the factory of William Neilson, Ltd., Toronto, who have built up a large business in the production of ice cream, and latterly in that of chocolate creams.

A representative of **The Power House**, who recently visited this plant, found that manufacturing was conducted on the most approved method, under adequate sanitary conditions, and with the aid of the latest machinery and equipment. The principal products are ice cream, ice cream bricks and chocolate-covered candies of various descriptions. The processes involved in their production will be described later.

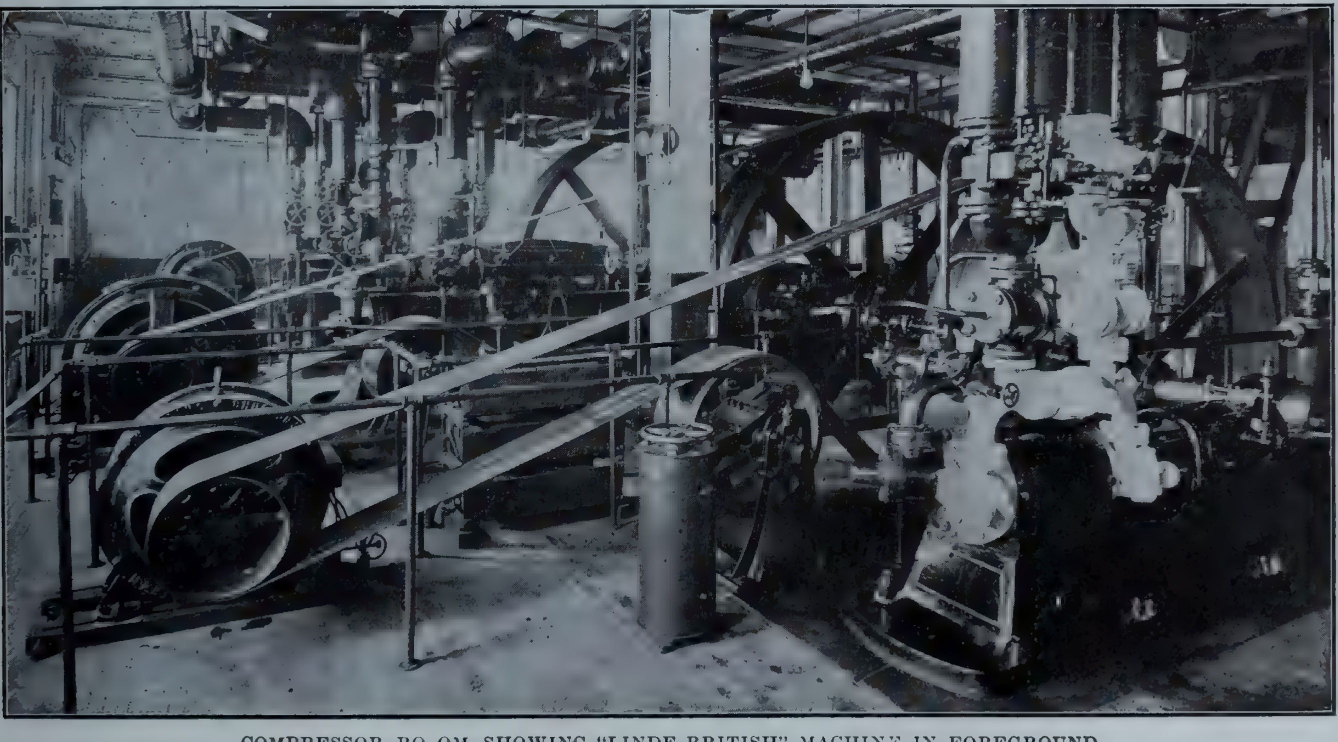
The main building is of brick construction, five storeys high, with a two-storey annex, containing the ice cream department, boiler and compressor rooms. The chocolate is made in the basement of the main building, while the offices occupy the main floor of the latter. The dipping and packing rooms are on the second floor, while on the floor above is the "centering" department, where the centre portions of the creams and similar products are made. The printing-room and stock-rooms occupy the fourth floor, and the fifth floor is devoted to the manufacture of paper boxes and cartons in which the product is shipped. In the annex on the ground floor is the shipping department, boiler-room, compressor-room, ice cream making department and freezers, while on the floor above is the can ice plant, cream-room and storage, carpenter and tinsmith shops.

The compressors and other equipment being motor-driven, steam is only required for heating and general purposes. In the boiler-room is installed a 50 h.p. return tubular boiler, 54-inch diameter and 12 feet long, supplied by Polsons Ironworks, Ltd., Toronto. The boiler feed is furnished by a duplex 4-6-6-inch pump.

Refrigerating Plant.

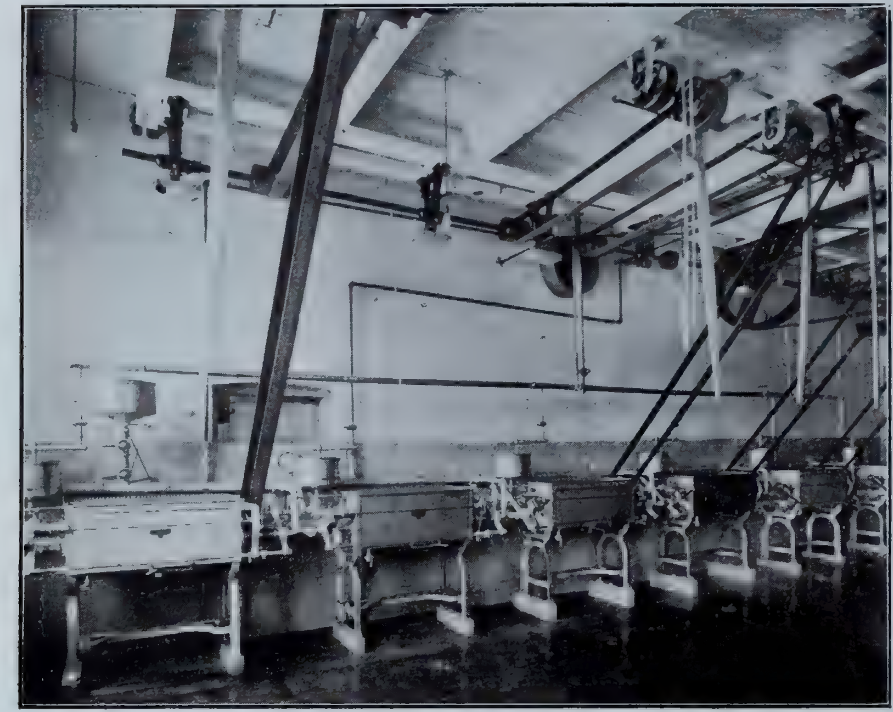
The compressor-room is about 60 x 80 feet, and contains three motor-driven, horizontal, double-acting ammonia compressors. The largest of these compressors is a 125-ton machine, built by the Creamery Package Manufacturing Co., Chicago, and installed about two years ago. It has a single cylinder, 16-in. diameter by 36-in. stroke, runs at 68 r.p.m., and is driven by a 175 h.p. C.G.E. induction motor, A.C., 550 volts, running at 500 r.p.m. The flywheel on this machine weighs approximately 16 tons. Another compressor is a 100-ton machine, with a single cylinder 16-in. diameter by 30-in. stroke, running at 62 r.p.m. This machine, installed about six years ago, was supplied by the then Linde British Refrigeration Co., Montreal, and is driven by a C.G.E. 150 h.p. induction motor, A.C., 2,000 volts, running at 500 r.p.m. The third and smallest compressor is also a then Linde British machine, installed about eight years ago. It has a capacity of 40 tons, the cylinder being 11-in. diameter by 18-in. stroke, and the r.p.m. 92. It is driven by a 60 h.p., a.c. motor of 550 volts and 720 r.p.m., supplied by the T. Harding Churton Co., Leeds, England.

All the machines have double return lines for operation with hot or cold compression when working in conjunction



COMPRESSOR RO OM, SHOWING "LINDE BRITISH" MACHINE IN FOREGROUND.

with the high and low temperature systems. They are all connected to the same piping system, the valves being so arranged that one or more machines can be out of the line when not required. The return lines are all fitted with thermometers, in order that the engineer may know if the correct amount of ammonia is passing through the system. By this means the plant can be kept under perfect control. Pressure gauges are also installed with each machine. After leaving the compressor, the gas passes through a discharge tank, which eliminates all water or oil that may have been carried over from the cylinders. The two Linde machines are equipped with rectifiers, connected up with the low pressure side, and a middle ring in the stuffing box to carry off any gas that may have escaped through the packing.



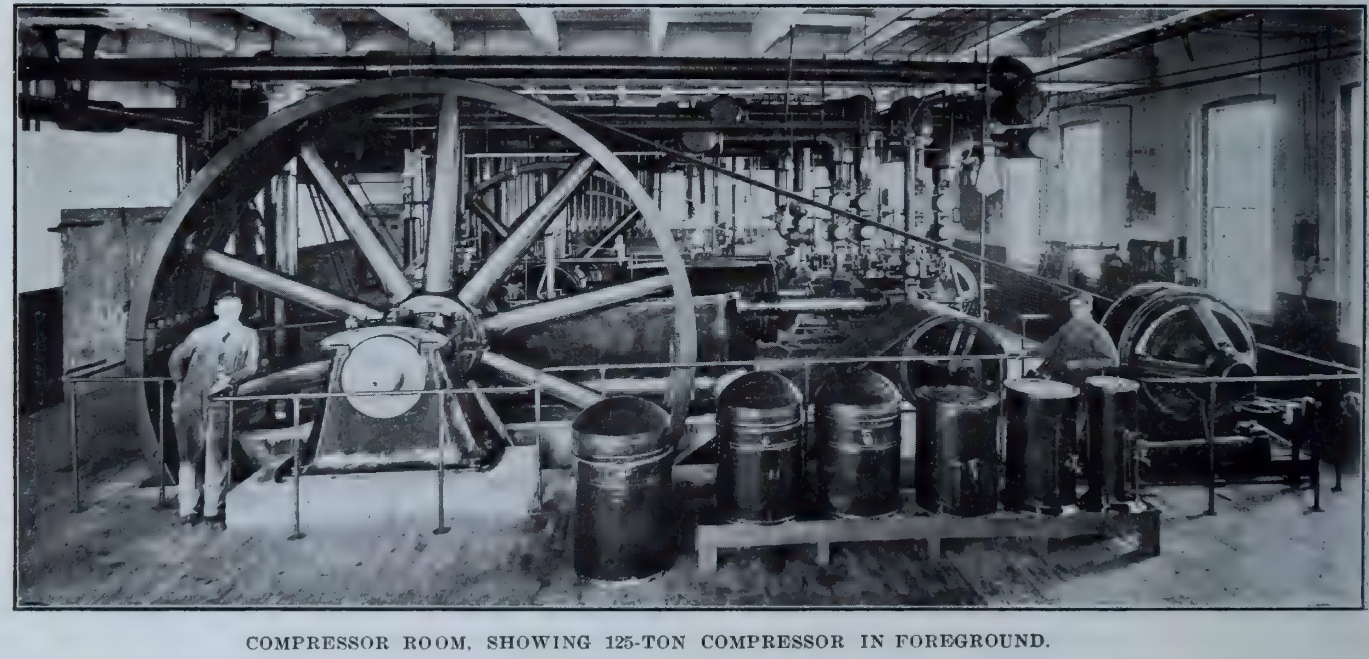
CREAM FREEZING MACHINES.

The condenser is located on the roof, and is of the double tube type, the inner or cold water pipe being 1¼-inch diameter and the outer or ammonia pipe being 2-inch diameter. The condenser is built in 17 sections, and is 18 ft. long by 18 ft. high. City water is supplied to the condenser, but in case the pressure is low, a booster pump is located in the compressor room to supply the deficiency. This is a "Smart-Turner" centrifugal belt-driven machine, with a capacity of 250 gallons per minute. The ammonia gas is pumped to the condenser at a pressure of about 150 pounds. The gas, cooling under pressure, forms a liquid which is carried down through the expansion valves in the compressor room, where the pressure is reduced to about 25 pounds in the direct expansion coils and 20 pounds in the brine tank coils. A thermometer is fitted in each line on the high pressure side of the expansion valve.

Hydro-electric current is used for driving the motors and lighting. The transformers receive current at 13,000 volts, which is stepped down to 2,000 volts for one compressor motor, to 550 volts for the other two compressr motors, and to 220 volts for the fan and pump motors. The lighting circuit carries 110 volts a.c. "Nonpareil" cork covering is used exclusively on all piping to freezing-rooms and brine tank, and was supplied by the Kent Co., Ltd., Montreal.

Can Ice Plant.

All the ice manufactured by the company is used for keeping the product cool during transit to the various stores and at the stores. The plant has a capacity of 362-400 pound cans, and consists of a large tank containing brine held at a temperature of about 14 degrees Fahr., and a number of coils containing ammonia at 20 degrees. The cans, filled with fresh water, are placed in the tank, and remain there for about 48 hours, when they are taken out by means of an air hoist attached to an overhead hand-operated traveling crane and exposed for a short period to a jet of warm water so that the ice will come away from the can readily. The process



COMPRESSOR ROOM, SHOWING 125-TON COMPRESSOR IN FOREGROUND.

consists briefly of the ammonia in the coils taking up heat from the brine, which in turn takes heat from the water in the cans, thus forming ice; the ammonia during the process becoming liquefied. Adjoining the freezing-room is an ice storage and two motor-driven ice-crushers in another room.

CENTERING DEPARTMENT, SHOWING DEPOSITORS AND MIXING KETTLES.

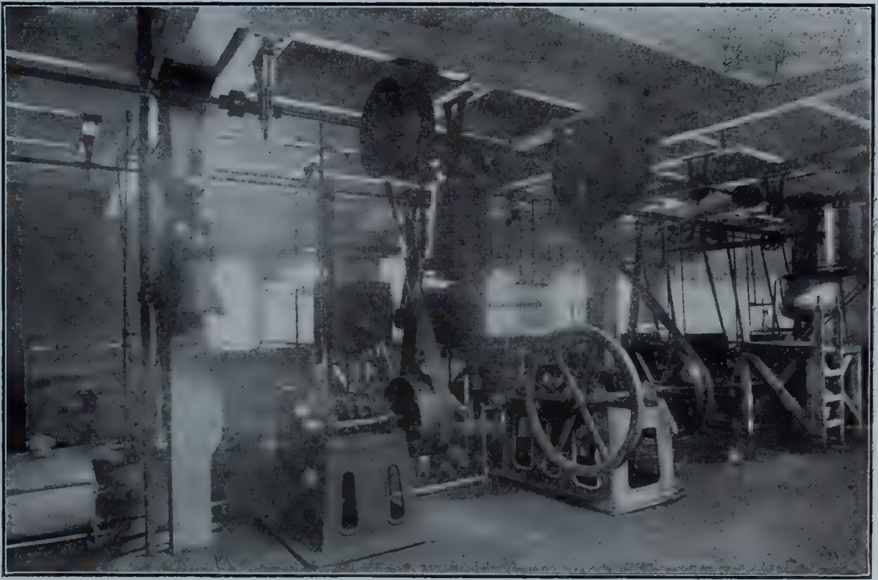
The brine tank is equipped with a propellor for agitating the brine, and air is supplied to the hoist by a "Curtis" air compressor located in the compressor-room. The machine is of the belt-driven, vertical type, single-acting, with cylinder 6-in. diameter by 8-in. stroke, and runs at 125 r.p.m.

Cooling Rooms.

In the manufacture of ice cream, cold storage rooms and freezers are essential. The can ice storage on the second floor already referred to is maintained at 32 degrees Fah. by 640 feet of direct expansion pipes. The cream storage on the same floor has a cubic capacity of 4,263 feet, and is held at 30 deg. Fah. by 600 ft. of direct expansion piping. On the main floor below, is the ice cream storage which has a cubic capacity of 9,200 feet, and is held at zero. This room is cooled by fan circulation, there being in an adjoining bunker 640 ft. of piping through which air is forced by a 36-inch "Sheldon" fan driven by a 5 h.p. motor. Adjacent is the ice cream brick storage of like capacity and temperature and cooled by the like method. On the same floor is the "brick" freezer which has 4,000 cu. ft., and is maintained at 6 degrees below zero. This room is also cooled by fan circulation, there being 2,500 feet of expansion piping and a 54-inch "Sheldon," fan driven by a 5 h.p. motor. The temperature of the storage in the chocolate dipping room on the second floor of the main building is 65 degrees. This room is cooled by fan circulation, there being 3,600 feet of expansion piping and a 70-inch motor-driven "Sheldon" fan.

Cream Room.

In the cream room the process consists of pasteurizing and homogenizing — adding the ingredients such as flavors, etc., to the cream, and mixing. The milk is first of all all pasteurized by heating in tanks shown on the left-hand of the illustration, to a temperature of 150 degrees Fahr., by means of a series of steam coils. It is then cooled in another tank to 90 degrees Fahr. The next process consists of homogenizing. This is done by passing the milk through a homogenizer, which is really a pump forcing it at a pressure of 150 pounds between the faces of a valve. This process permanently combines the contained milk and cream, thereby ensuring uniformity in the quality of the ice cream. There are two homogenizers with a capacity of 150 and 300 gallons per hour respectively. They are both belt-driven and were supplied by the Manton, Gaulin Mfg. Co., Boston, Mass. After leaving the homogenizers, the cream is first cooled by passing through a series of air-cooled coils, and afterwards into tanks containing a number of copper pipes through which brine flows; here the temperature of the cream is reduced to 36 degrees Fahr.



CREAM ROOM, SHOWING PASTEURIZERS AND HOMOGENIZERS.

The next process consists of mixing the cream and ingredients together thoroughly before being carried to the freezers. There are four mixing tanks, each containing a revolving cylinder and operated from a belt-driven shaft running along the front of the tanks. The outlet from each tank is connected to a pipe through which the cream flows to the freezers below and the piping is so arranged that any one or more tanks can be used when the others are not in service. The first mixing tank only is equipped with a cooling arrangement, which consists of a water-box at the end of the tank containing brine coils, over which water flows to the interior of the revolving cylinder. A 2-inch centrifugal pump circulates the brine through the coils in the cooling tanks. The pasteurizers, cooling and mixing tanks were supplied by the Creamery Package Mfg. Co., Chicago.

Cream Freezing.

The cream freezers, "brick" freezing rooms and cream storage are located together on the main floor. There are six freezers, having a total capacity of 600 gallons per hour. In each freezer are two revolving coolers containing brine at 6 degrees Fahr., and connected with a brine system, circulation being provided by a 2-inch centrifugal pump. The cream from the mixing tanks on the floor above flows down direct to the freezers, from which it is drawn off when it has reached the proper consistency. The cream for the bricks is drawn off into shallow trays and placed in the brick freezer where the temperature is 6 degrees below zero. The freezers were supplied by the Creamery Package Mfg. Co. The bulk storage and brick freezer rooms are insulated with 6-inch "Nonpareil" cork and are equipped with "Stevenson" doors.

The brick-cutting room is on the main floor near the freezing room. Here the blocks are cut in a brick-cutter, 32 bricks being made at one operation. The bricks pass along a table where they are wrapped and put on a belt conveyor which runs over another table over which is a carton or box hopper. The boxes come down a chute from the box-making room into the hopper. The bricks are next packed in the boxes and sent to the shipping room.

Chocolate Making.

The various departments and processes which have been already described are all connected with the refrigerating end of the plant. The remaining departments while of considerable importance from a manufacturing standpoint are not so closely allied to the refrigerating plant as the others, therefore a brief description will only be given of these.

The most interesting section from a mechanical standpoint, apart from those already described, is perhaps that devoted to the manufacture of chocolate. The machinery is of the latest type and represents a considerable outlay. The greater number of the machines were supplied by the J. M. Lehmann Co., New York and Paris. A large quantity of chocolate is used, and this calls for a plant of sufficiently large dimensions to take care of the demand. This department is located in the basement of the main building, the location being readily determined by the pleasant aroma emanating from it.

The cocoa beans are imported from the West Indies and other countries. The beans are first of all cleaned in a special machine, then roasted and cracked. They are next ground in mills to a fine powder after which the ingredients are added. The mixture then passes through two refining mills and finally is worked up into a thick paste in a "conche" machine, when it is ready for the dipping-room. There is also installed a sugar pulverizer. The machinery in this department is driven by a 50 h.p. Can. Westinghouse a. c. motor.

The "centering" department is on the third floor and is where the cream centres are made. The ingredients are mixed together in steam-heated mixing kettles, the cream being further treated in a cream beater. Moulds for the reception of the various mixtures are made in starch laid on wooden racks, the impressions being made in the starch by plaster of Paris patterns also arranged on wooden racks. A machine called a depositor having been filled up with cream or other mixture, the moulds are placed underneath and the cream poured into them. When the creams have set, they, together with the racks, are put into a "starch buck" where separation takes place, the creams being carried to the dipping room on the floor below. In the dipping-room, the creams are covered with the chocolate and laid in the cooling room to set. They are then carried to the packing room and prepared for shipment.

The Company make their own paper boxes and labels. On the fifth floor is installed machinery for making the boxes and cartons and for fixing the labels. On the floor below, the labels are printed and made to the required shape and design. Part of this floor is used as a stockroom. A Turnbull elevator, with a capacity of 2,000 pounds and motor-driven, serves all the floors, and a fire protection system is installed throughout, while lavatories, and other comforts and conveniences conducing to the welfare of the employees, who number 275, are provided on each departmental floor. The ice cream output in summer amounts to 6,000 gallons per day, and in winter, when the demand is naturally less, the average is about 400 gallons per day. The management and direction of the factory is vested in the following officers:—

William Neilson, president.

Morden Neilson, manager and secretary.

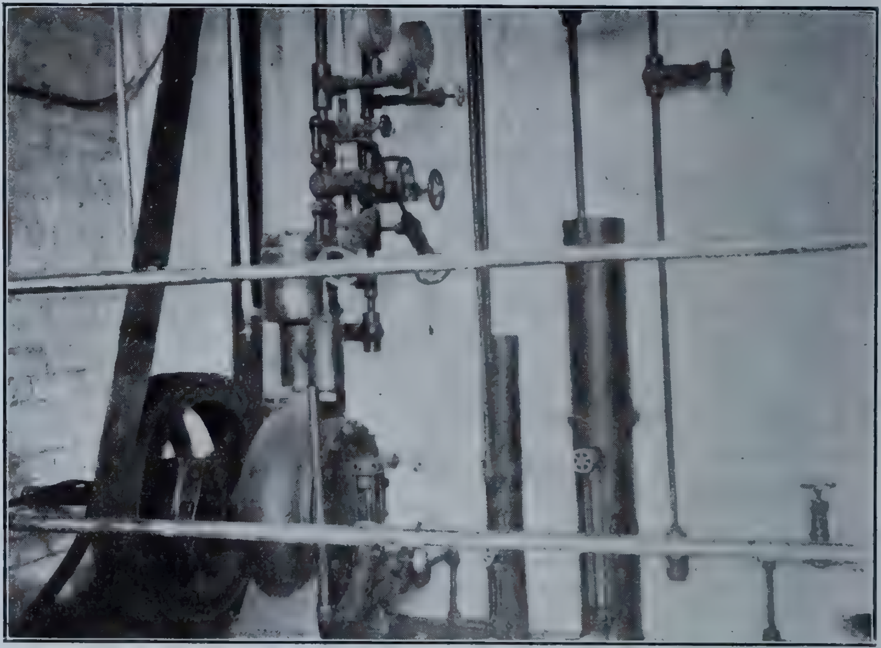
Allen Neilson, superintendent.

D. Madill is chief engineer.

MODERN DAIRY INSTALLATION.

THE illustration shows a 1-ton "Brunswick" ammonia compressor installed at the Wm. Muir dairy, West Toronto, for cooling a milk storage and brine system for a milk pasteurizer. The machine is of the vertical, single acting type with enclosed crank case and oil splash lubrication. It is equipped with ammonia receiver, oil separator, expansion valve, and scale trap on suction side for retaining any scale or dirt, etc., that might get into the system. The valves and pipe joints are ground metal to metal, and the discharge valve is the full diameter of the cylinder. The compressor is driven by a 2½ h.p. motor situated on the top of the cooling room.

The condenser is fixed to the wall above the compressor and is of the double pipe type, water cooled, and connected to the high pressure side. The low pressure side is connected to a set of direct expansion coils located in the cooling room. On the wall of this room is a brine tank of flat construction, containing a series of coils for cooling the brine. This arrangement maintains the temperature of the room when the compresor is not working. On the top of the cooling room is another brine tank containing a series of coils connected with the direct expansion piping. The brine from this tank is pumped through the coils in the pasteurizer in order to cool the milk after being pasteurized. The cooling room construction consists of 4-inch "Nonpareil" cork-board, with cement plaster coat on both sides. The compressor and other equipment was supplied by W. A. Drummond Co., Toronto.



ONE-TON BRUNSWICK COMPRESSOR, WM. MUIR DAIRY.

BOILER EXPLOSION AT OTTAWA.

A DISASTROUS boiler explosion occurred on the morning of January 21 at the Howick Hall, Ottawa, when three men were killed, five severely injured, and several valuable horses perished. The Eastern Ontario Live Stock Show was being held at the time, which accounts for the presence of the horses. The hall is a steel and concrete structure, with an annex, about 150 yards square at one end, built of wood. It was under this section that the boiler and heating plant were located.

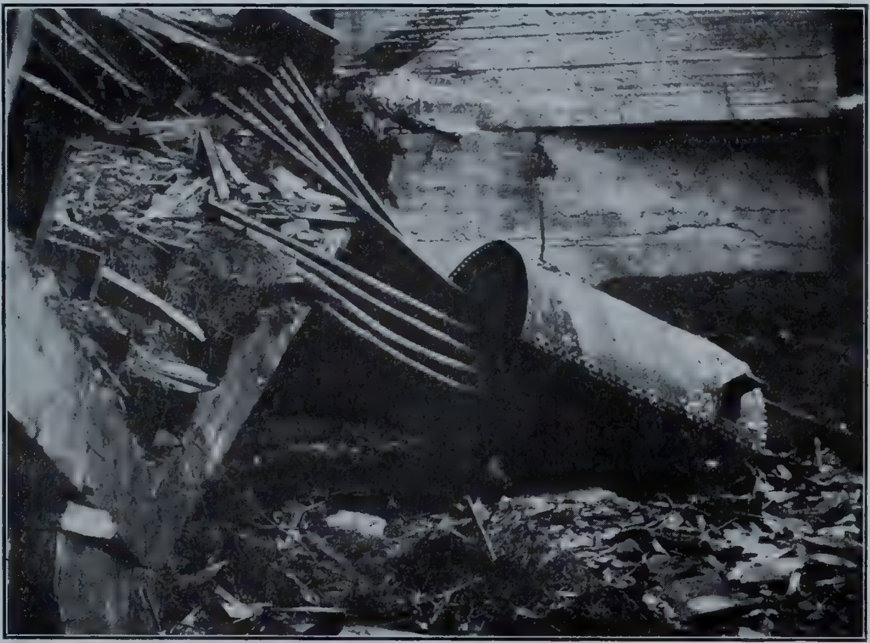
The boiler was of the return tubular type, 60-inch diameter by 14 fet long, and had 82 3-inch tubes. It was made of Carnegie steel plate of 60,000 T.S., 5-16-inch thick, the heads being ⅜-inch thick with 1⅛-inch longitudinal stays. The longitudinal seams had double riveted lap joints with ¾-inch rivets, 2⅞-inch pitch. The girth seam was a single-riveted lap joint having ¾-inch rivets, 2 1-16 inch pitch. The safety valve was of the lever and ball type, 3½-inch diameter. The boiler failed at the manhole ring, which was of cast iron, and through the front shell plate in a longitudinal direction.

At the official enquiry, held to investigate the cause of the explosion, the jury brought in a verdict to the effect, "that the explosion was caused by excessive steam pressure and that the safety valve and steam gauge were defective." According to the specification, the boiler was good for 65 pounds working pressure, but it had been operated at a lower pressure, usually around 20 pounds, and was used for supplying steam to a low pressure heating system. We are indebted to Mr. D. M. Medcalf, chief boiler inspector of the Province of Ontario, for the constructional details and accompanying photographs. Mr. Medcalf made an examination of the wrecked boiler on behalf of the Provincial Government.

THE WEATHERING OF COAL.

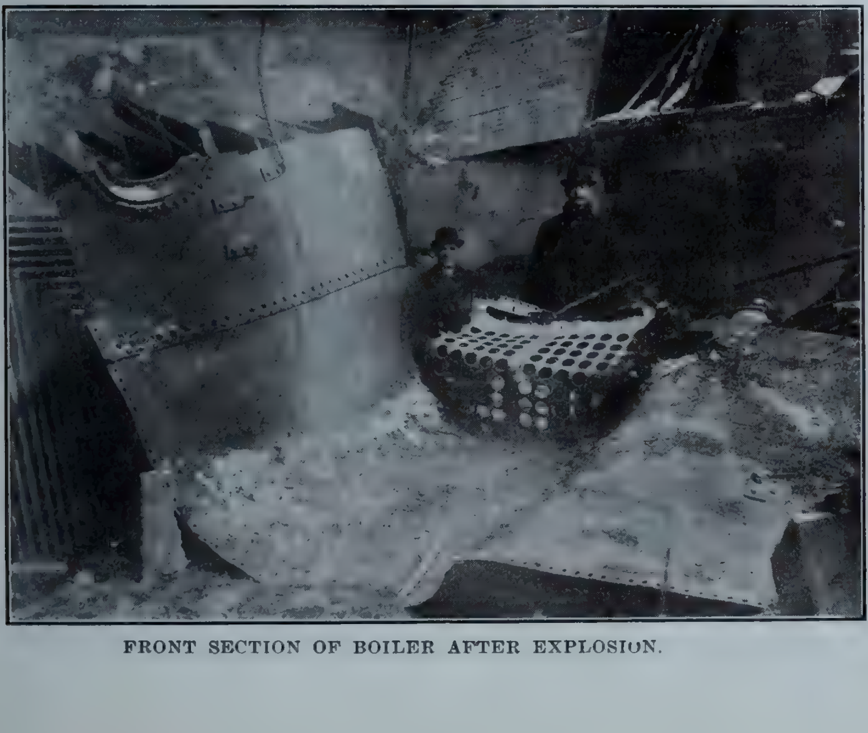
MUCH has been written on the weathering of coal, says a writer in the Power User, and generally speaking it has not borne out the complaints that are made as to the capacity of weathered coal for steam raising. There are several actions at work when coal is weathered.

First, there is the actual contact of the atmosphere. When coal becomes hot in a pile it is because it is being slowly oxydized, and there is not sufficient cooling at work to keep down the temperature. Now, if coal can oxydize in this manner it is being destroyed as coal. Probably in a closely-packed heap a very small amount of heat will produce a considerable temperature, for the heat is locked in, and all accumulates until a high temperature is attained. Then, if air be admitted, the heap may fire. Some deterioration must have occurred, for a coal cannot be twice oxydized, and once it has been hot some of its calorific value has passed off. It is said also that once coal has become hot in the heap and has cooled down, it will not again become hot. It would thus appear that there may be some principle in coal which is specially ready to oxydize, that its amount is small, and that once having heated there is none left to repeat the process.



REAR SECTION OF BOILER AFTER EXPLOSION.

In recent years it has been observed that coal dredged up from salt water, where it has lain many years, is quite uninjured. It has been kept cold, away from contact with air, and has not been knocked about, and, we believe, steps have been taken to provide under-water storage for coal at the coaling stations of the Navy. A further advantage is that such coal ceases to be a grimy nuisance as soon as it is submerged, and also that it is effectively fenced against all possibility of fire. Various reports and papers have appeared in different publications on the weathering, heating and storing of coal but, at the moment the writer cannot locate these. Coal is probably a very complex substance, but very little is known of its actual constitution. It can be analyzed for its ultimate elementary constituents—so much carbon, hydrogen, sulphur, oxygen, nitro-



FRONT SECTION OF BOILER AFTER EXPLOSION.

gen, so much silica and alumina, and small quantities of iron and other elements. If distilled at a high temperature, it will give off a certain number of products, compounds of the foregoing elements. If distilled at a low temperature, a different set of compounds are given off, but it cannot be said even that these are present in the coal. Rather they are present out of the coal.

It is not known how the atoms of the chief constituents are bound together. The products of distillation are apparently formed in the process of distillation, for if they were in the coal in the same chemical combination in which they are distilled off, the same compounds would come off at different temperatures. Thus we know more of the plant and animals of which coal was formed ages ago, than we know of its chemical constitution to-day. We do know that compounded with a very little hydrogen, carbon ceases to be a very infusible substance and becomes gaseous, liquid or plastic, and all these states of carbon may be obtained if coal be heated; but coal at ordinary temperature exhibits no trace of such other states of carbon. It is, therefore, not easy to trace the results of weathering, of slow or partial oxidation. The mere fact that mechanically coal is so very friable, especially some of the highest qualities of it, should, however, be sufficient to make it imperative to avoid as far as possible both roughness of mechanical treatment and exposure to atmospheric influences.

RUNNING DIESEL OIL ENGINES.

IN the event of a Diesel type engine not running properly, says the Engineering Review, the cause or causes should be investigated without delay; and the following information will be found of considerable service in showing how defects may be remedied.

If, after starting-up on air and the fuel oil is admitted to the engine, firing does not occur, it should be ascertained whether:—

(a)—The fuel filter cock is open.

(b)—There is enough oil in the nozzle.

(c)—The fuel pump contains air, discovered by bubbles rising on disconnection of the delivery pipe.

(d)—The fuel pump valves are loose, or their seats corroded.

(e)—The exhaust or intake valve-cages are loose, preventing the necessary rise in cylinder air-pressure.

(f)—The oil fuel fails to flow through the pipes, due to excesive viscosity.

(g)—Water has found its way into the fuel oil.

(h)—The suction valve is loose, discovered by applying pressure from the air injector bottle.

It should particularly be observed that, although on disconnection of the delivery pipe the fuel pump may deliver against atmospheric pressure, it may be incapable of supplying oil under the pressure of injection. Knocking is caused by (a)—the pressure of the injection air being too high; (b)—the needle in the fuel nozzle being loose on its face; or (c)—the orifice in the flame disc being too wide.

Should an exhaust valve not lift easily, observe whether the spring is broken; or whether the seating is corroded with carbon or soot. In the latter case, a very small quantity of paraffin may be used to free the spindle and guide.

A smoking exhaust indicates that:—

(a)—There is overloading.

(b)—The fuel oil is unsuitable.

(c)—The air pressure for injection is insufficient.

(d)—The starting, air, or exhaust valves are loose.

(e)—The needle of the fuel nozzle is loose, the pulverizer is dirty, or the orifice in the flame disc is choked.

(f)—The piston head is dirty.

When the governor motion is excessive or irregular, then the dash-pot piston jambs, the control rods are prevented from working easily, or the valves of the fuel pump are loose.

Defective working of the air-compressor pumps may be due to:—

(a)—The valves being dirty or loose.

(b)—Foreign matter in the inter-coolers.

(c)—The piston rings sticking from lack of lubricant, or being rusty from the presence of water in the inter-coolers.

(d)—Excessive clearance in the air chamber.

Partial loss of pressure in the air bottles may be in consequence of defective valves, or their not being screwed down tightly enough. Should complete loss of air pressure occur, the motor may be started on carbonic acid gas. Great care must be taken in this operation that all connections are in order, and all valves are ready to work properly. The vessel which holds the carbonic acid is set close to the starting bottle, and a suitable pipe fixed on to the unions provided for the purpose on these bottles. If it be found that the pressure in the injection bottle is less than that in the starting bottle, supply the injection bottle from the starting bottle first, and before the valve of the latter is opened for the admission of the carbonic acid.

Stoppage of the motor may be caused by:—

(a)—Partial or complete cessation in the fuel feed.

(b)—Water in the fuel oil.

(c)—Jambing of the exhaust valves.

(d)—Overload.

(e)—Seizing of the air compressor piston from lack of lubricant.

(f)—Seizing of a main bearing from insufficient oil, manifested by the absence of crank oscillation on stopping.

Where a compressor of the Reavell type is employed, it is necessary that the mechanism be kept scrupulously clean, and lubricating oil of good quality be used. Indifferent lubricant is extremely liable to stick the piston rings, so that much of the air pressure escapes. Moreover, the air volume may be rendered insufficient in consequence of foreign matter or carbon on the faces of the valves and their seatings. Unless a full body of water be maintained in circulation, rapid heating will occur, thus causing carbon deposit which will affect proper compression.

Should a rise of pressure take place in the intermediate receiver, the high pressure or delivery valves must be examined for leakage. This operation is effected by opening the drain cock on the intermediate purge pot and allowing full pressure to enter from the air tank above the high-pressure delivery valve.

(a)—If air escape from the cock, then the high-pressure intake and delivery valves are both leaking, but, even though no air escapes, one of these valves may be loose, because, if one of them seats correctly, that is alone sufficient to stop a leak into the intermediate purge pot.

(b)—By removing the high-pressure delivery valve, replacing the cap, and re-admitting the pressure to the high-pressure cylinder, the defective valve may be discovered. Leakage in the high-pressure intake valve is shown by air escaping from the drain-cock of the intermediate receiver; and should the valve be tight, air must be admitted behind the delivery valve, after removal of the intake valve, from the seat of which air will escape if the delivery valve is leaking. The same methods are applicable in the event of pressure increase in the low-pressure receiver, and these are effected between the low-pressure and the intermediate cylinders, the high-pressure intake and delivery valves being detached. For testing, the air pressure should not exceed approximately 100 lb. in the low-pressure reciver, and 400 lb. in the intermediate chamber.

◆

Ottawa, Ont.—The Board of Control has appointed G. E. Sims, Montreal, to prepare plans for the erection of a municipal abattoir, for which it is proposed to erect a two-storey concrete and brick building, with capacity for 50 cattle, 75 hogs, and 110 sheep. The city will issue debentures for $100,000 to provide for its erection and equipment.

THE BUSINESS OUTLOOK.

TO all appearance the business depression in Canada struck bottom some time since, if we might judge by the reports of improving tone in the machinery and allied trades. Easier money conditions now prevail, and what is perhaps the most potent feature of all, people generally have become optimists. As remarked on a previous occasion when the descent was still in progress, everybody was lending their weight to accelerate it, and as becomes human nature, all hands are now engaged in the elevating process.

The development and progress of Canada, dependent though it be to a large extent on conditions in other countries must go on, and in this connection there is just the possibility that more of the financial assistance so generously received from Great Britain will this year be forthcoming, if, as is generally believed, the crest of the wave of industrial prosperity there was reached in the closing months of 1913.

◆

ARITHMETIC FOR MECHANICS AND ENGINEERS.

BEGINNING with the present issue of **The Power House**, and accompanying each month the **Questions and Answers for Engineers**, a course of lessons in **Workshop Arithmetic** will be given, and in order that it may have the fullest scope, the subject matter will be treated right from the foundation upwards.

Arithmetic in the workshop, factory and power plant is to-day perhaps a more necessary requirement than at any previous period of industrial history and enterprise, and conducing as it does to the cultivation of a sharp and clear intellect, in addition to facilitating and systematically contributing to high degree quantity and quality production, as well as to the advancement of the individual, there is no reason why beneficial results should not follow the study of each lesson, even by those who have got beyond what will be the necessarily introductory part.

◆

TENSION ON CYLINDER COVER STUDS.

THE article which appeared on pages 21 and 22 of our January issue, entitled **Tension on Cylinder Cover Studs**, appears to have touched a responsive chord in the heart and head of quite a large circle of the readers of **The Power House**. We say heart as well as head because of the large number of expressed opinions received for publication, it being a well-known fact that timidity or want of heart courage has been and is robbing the pages of technical journals by retaining in more or less obscurity a myriad forms of high degree inventive genius with its resultant accomplishment. We refrain from making comment meantime on the particular question under discussion, it being sufficient as well as gratifying to know that given the opportunity to cultivate and develop their beings along the line of higher grade intelligence, most men will quit the groove of the automaton.

There is an impelling attractiveness and fascination in analyzing and figuring out problems involving more or less arithmetical calculation, and even although in some cases there may be an unconscious disposition to read into them more than is really involved, the ultimate results are all on the credit side. The features, however, that make study of this nature more valuable are the knowledge that a collective intelligence is being concentrated on the work of each individual, and that a corresponding benefit thereby accrues. There is absolutely no necessity for an operator harboring uncertainty in his mind, at this time of the day, as to the why, wherefore and proof of design and detail of mechanical engineering construction, and if a little more heart—pluck if you like—were brought to support the head, by readers bringing their difficulties and problems out into the open so that others could join in and help the originator and themselves, the standard of operative ability would be materially raised, and greater achievement of the craft would be made easily possible.

Another set of readers' opinions on the problem will appear in our March issue, lack of space limiting the publication of all of those received in the present instance.

◆

Claiming to be, and being what is claimed, usually are two different things. No man who measures up to his claims need say anything, it will be apparent.

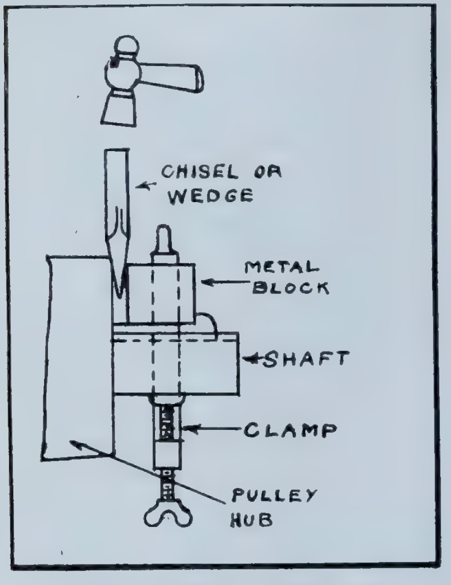
THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

HOW TO PULL A TIGHT KEY.

By N. G. Near.

THERE is shown herewith a little scheme that I have found useful for pulling tight keys. The drawing makes the operation self-evident. The metal block is thicker than necessary in order to show the method more clearly. It is, in fact, better to use a thinner block thus making the overturning movement less. Of course the exact arrangement illustrated need not always be strictly followed, there being a hundred and one variations based on the same principle.



HOW TO PULL A TIGHT KEY.

* * *

TENSION ON CYLINDER COVER STUDS.

By A. E. W.

IN the January issue of **The Power House** there appeared an article under the above heading, by J. H. Rodgers, in which the old question is raised of whether the tension in cylinder cover studs is increased when steam is admitted to the cylinder.

It is generally agreed that with a metal-to-metal joint no increase in the tension on the studs takes place until the force tending to separate the cover from the flange exceeds the initial tension in the studs due to the screwing up of the nuts. If, on the other hand, an elastic packing be inserted in the joint, the tension on the studs is equal to the initial or "screwing-up" tension, plus the tension due to the steam pressure. This second conclusion is correctly arrived at by Mr. Rodgers, and is illustrated by his Fig. 8. His Fig. 1 also shows conditions as they are, but he makes the mistake of saying that if the weight on the cover were only 10 lbs., the stress on the studs would be 1,005 lbs.

In order to secure a steam-tight joint it is, of course, necessary that the cover and flange be made thick and rigid. When the cover and flange are pressed together, metal-to-metal, they are much more unyielding than the studs or bolts. If the flange and cover are assumed to be so heavy and rigid that they cannot be compressed at all, the studs are practically springs, and, in order to produce in them a tension higher than the initial tension, a force must be applied to the cover sufficient to separate the latter from the flange.

Referring to the accompanying Fig. 1, let it be assumed that each nut is screwed up so tight that its stud is elongated 1-1,000 inch, and, in order to use the same figures assumed by Mr. Rodgers, we will suppose that this elongation produces a stress of 1,000 lbs. in each stud. The cover is thus pressed upon the flange with a force of 1,000 lbs. for each stud. Only two studs, as seen in the figure, need be considered. We have then a force of 2,000 lbs. holding the cover to the flange.

If a weight of 800 lbs., as shown at (A), be now placed on the cover, it is obvious that no extra stress is set up in the studs. For they cannot be stressed beyond 1,000 lbs. without being at the same time further elongated, and they cannot be further elongated unless we separate the cover from the flange, to do which will require a force of slightly over 2,000 lbs. The only effect of the weight (A) is to reduce the pressure between the cover and the flange by 800 lbs. If, however, the weight (A) be increased to 2,000 lbs., the studs will be stretched a further 1-1,000 inch, and the joint will open. This result has been embodied in the following rule:—

When the bolt, or stud, is more elastic than the material it compresses, the stress in the bolt is either the initial stress or the force applied, whichever is the greater.

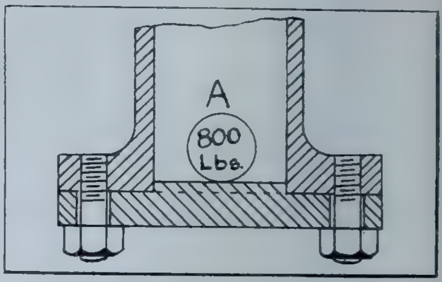


FIG. 1. TENSION ON CYLINDER COVER STUDS.

The Elastic Joint.

Next consider the conditions existing when a packing or gasket is introduced at the joint, as shown at (B), Fig. 2. In such a case, it is the packing rather than the stud that is elastic. Let us assume that the studs are again stressed to 1,000 lbs. each, and that this compresses the packing 1-100 inch. If now the weight (C) of 800 lbs., as before, be applied, the studs will be stretched an inappreciable amount compared with the amount the packing has been compressed. The result is that the packing will be pressed against the flange with practically the same force as before, and the only effect of the weight (C) is to increase the stress in each of the studs by 400 lbs. In other words, the stress in the studs is the initial stress, plus the

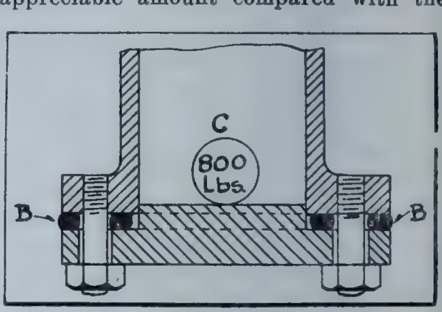

FIG. 2. TENSION ON CYLINDER COVER STUDS.

stress due to the force tending to separate the cover from the flange. Hence the second rule:—

When the material compressed is more elastic than the stud, the stress in the stud is the sum of the initial stress and the force applied.

◆

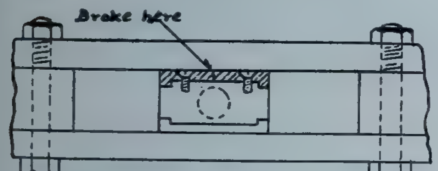
REPLACING CROSSHEAD LINER.

By R. Bell.

ON an engine of the double bar type there were brass liners fixed to each side of the crosshead shoes. These were secured by means of ⅝-in. countersunk headed screws, and further held in place by a shoulder at each end as shown in sketch. One of these liners got working loose, and eventually broke in the middle, so it had to be replaced, being unsafe. A very quick and effective repair was made as follows.

The top guide bar was taken off and the liner removed. The guide block was cleaned properly and then replaced. The engine was next turned over until the crosshead stood in the narrowest part of the guide bars, these being worn a little in the centre. The open edges were then boxed up with wood and all small spaces filled with clay, provision being made for a runner to allow the babbitt to be poured in. The space formerly occupied by the liner was now filled with babbitt, boxing removed, a liberal supply of valve oil applied to the guide bar and the engine started up. The result was a first-class job started and completed during the lunch hour.

I am of the opinion that babbitt might be used more extensively than it is for repairs such as the above-mentioned. It makes a substantial and satisfactory job, does away with all machining.

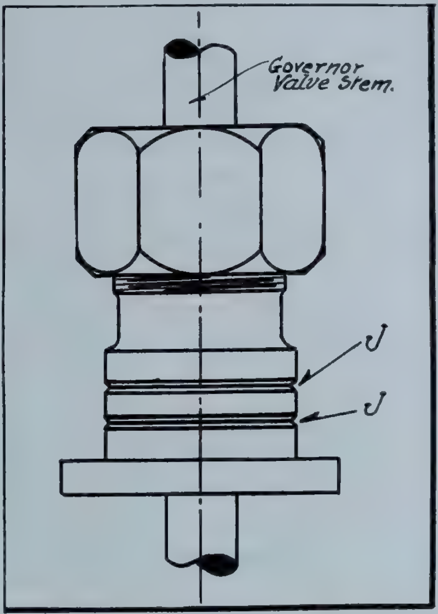


◆

LEAKY STUFFING BOX REMEDY.

By J. E. McCormick.

ON an old engine, the governor spindle stuffing box had been turned to tightly fit into the hole drilled for it in the top of the governor valve chamber and had been thus forced into place, but after long service it had become so loose as to develop a disagreeable leak. I remedied the latter by cutting two grooves as indicated in the sketch. As a small ridge was formed on each side of each groove, it increased the diameter between these points, and by going lightly at first and frequently trying it in place, a snug fit was easily secured at both grooves and the part again forced into place. By fitting and finishing the lower groove first, I was able to fit each groove independent of the other.



LEAKY STUFFING BOX REMEDY.

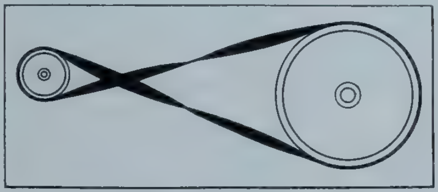
This repair was made three years ago, and although no lead or other substance was used, there has been no leaking since. I believe this method of "expanding" may be adapted to some other items of repair work where a tight fit is required in a joint requiring no movement between the parts.

◆

RUNNING A CROSSED BELT.

By J. E. McCormack.

WHEN running a crossed belt on two pulleys, one of which is only one-third, more or less, the diameter of the larger pulley, try putting the belt on the smaller pulley first; then, after crossing it, turn the remaining loop inside out, other side to the pulley, before placing it on the latter. This belt will now scrub its edges less than if put on in the usual manner. Of course, as one side comes in contact with one pulley and the other side comes in contact with the other pulley the joint must be laced or fastened accordingly. The foregoing method will not apply when the difference in the pulley diameters is comparatively small.



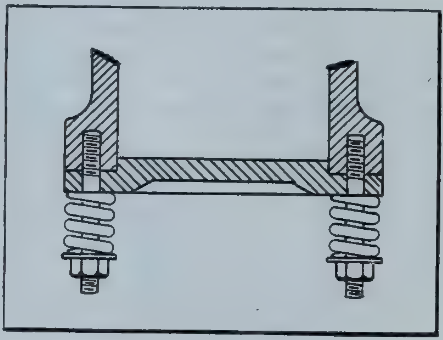
RUNNING A CROSSED BELT.

STRAIN ON CYLINDER HEAD STUDS.

By H. Westwood.

AS this is a question about which there ought not to be any difference of opinion among engineers, and as there is some danger that some who ought to understand it, may not consider it worth their while to figure it out, I beg to submit the following explanation:—

Assume that ten studs securing a cylinder head to the cylinder are long enough to permit a heavy coil spring on each one in such a way that one end of it will press against the outside of the cylinder head, and the other end against a washer placed between it and the nut on the stud. If the nuts be now screwed up, so that each spring is under a tension of say 1,000 lbs., there will be a total pressure of 10,000 lbs. against the head tending to hold it up to the end of the cylinder. As the springs will exert an equal pressure in both directions, there must be a tension of 10,000 lbs. on the studs. It will now be readily understood that all the strain there is on the studs is that due to the action of the springs, and that this cannot be increased except by further compression of the springs. This can be done from the inside of the cylinder by turning on the steam and as soon as the pressure rises in the cylinder there is certainly more stress on the studs by further compression of the springs, thereby forcing the head away from the cylinder and shortening the distance between the cylinder head and the washers under the units.



STRAIN ON CYLINDER HEAD STUDS.

To those who find this proof convincing, it may be well to suggest that the part performed by the springs in this particular case is ordinarily taken by the elasticity of the studs which act precisely in the same manner, and it may be well to say further that the above action in regard to bolt strains, is not confined to cylinder head bolts only, but is true in all cases where a bolt or a stud is subjected to tensile strain.

◆

Flywheel Query.—H. Westwood, Stratford, Ont., has sent in the following problem for solution by readers:—A flywheel 12 ft. in diameter, and weighing 10 tons, revolves at a speed of 150 r.p.m. It is built in halves, these being secured by four 2½ in. bolts at the hub, and by four 2-in. bolts at the rim. If there is a tensile strain of 1,000 pounds on each of the hub bolts and 700 pounds on each of the rim bolts when the engine is standing, how much strain is there on the respective bolts when the engine is running at normal speed?

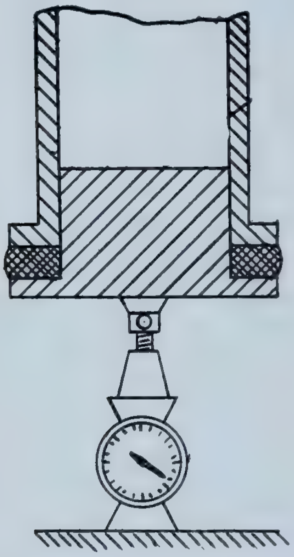
◆

TENSION ON CYLINDER COVER STUDS.

By R. Bell.

I READ with interest the article, entitled "Tension on Cylinder Cover Studs," by J. H. Rodgers, in the January issue of The Power House. From such articles there is certainly a great deal of benefit to be derived, and especially by us in the outlying districts of this western land, where we are out of reach of technical schools and other such excellent institutions.

While the answer may seem very clear to each of us, whatever may be our opinion, still there is always the other side to consider, and, in doing so, we may have to hunt out some of our old text-books, which may have the dust of years on them, though they ought not to have; and, although we may not get any new light on the point at issue, still we are the gainers by having considered two sides of some problem, which, perhaps, never before crossed our minds. Could we but have some such question brought before us each week and debate it out in our own minds or with our fellows, many a man would get out of the rut and become a thinker instead of a mere machine.



With regard to the question raised, I am of the same opinion as Mr. Rodgers. The pressure on the studs does increase, and the figures shown in the article demonstrates to my mind quite clearly the conclusions arrived at. I reason it out in this manner. The sketch shows a cylinder and cover which, for the sake of demonstration, is made so that the cover is free to move through a certain distance. The spigot of the cover goes well into the cylinder, and is steam-tight where it fits into the cylinder. There is further a compressable joint between the cylinder and cover. The area of the cylinder is 100 square inches. Suppose the cover, instead of being held in place by studs, to be blocked up by means of a strong steel balance and have pressure applied by a screw jack interposed between the balance and cover until the balance shows 10,000 lbs., being the pressure mentioned in the original question raised by Mr. Jones; in other words, ten studs screwed up to a tension of 1,000 lbs. each.

Now, I hold that for every 1 lb. per square inch of steam pressure admitted to the cylinder the balance will show another 100 lbs. The pressure mentioned in the question is 80 lbs. per square inch, and this on an area of 100 square inches would be 100×80=8,000 lbs. Our balance at this pressure would, therefore, register 10,000+8,000=18,000. The balance is taking the place of studs in this experiment, and if the balance indicates this extra pressure, why should the studs likewise not receive it?

With regard to the question raised by Mr. Orr: "Does the pressure of steam against the inside of a cylinder cover lessen the screwing-up presure with which the studs hold the cover against the cylinder end?" I should say it certainly does, and that pressure reaches zero when the pressure exerted on the inside of the cover is equal to the total tension on the studs holding the cover in place. The tensile strength of the studs, of course, continue to hold the cover in place after that point is reached.

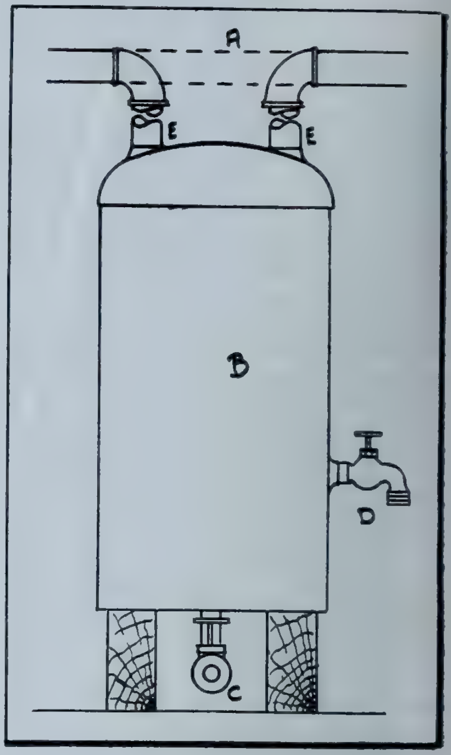
◆

GETTING RID OF THE SAND.

By J. E. N.

AT the present time, Toronto engineers are having loads of trouble in the shape of loads of sand, being carried in the cold water supply to their hot well and other pump features and fixtures. Brass plungers, valve seats and packing are being destroyed by the sand which the Water Commissioners are supplying at the price of water. Now this state of affairs may be pie to the builder who has to simply open up a valve and allow the sand and water mix-to flow gently over the lime, although there may be more sand than water. With the poor engineer it is a different story, for he has to stay late at night, and maybe work Sundays to repair the damage caused by sand during the week's run.

Here is the scheme I am using with success to get rid of the sand before it reaches the pumps, etc. Originally, the one inch iron pipe feed had a straight run, as shown at (A) by dotted lines, I secured a 100 gallon range boiler (B), cut out the piece of pipe at (A), and connected the boiler as shown. The water enters at (E) and leaves at (F), while the sand falls to the bottom and is blown out at intervals by the valve (C). The hose for washing out, etc., can be connected to the cock D.



◆

The Kent Co., Ltd., Montreal, representing the Armstrong Cork Co., Pittsburgh, have recently put on the market what is known as a "Nonpareil Insulating Brick." The brick is 9 x 4 x 2½ inches, of light terra-cotta color, and weighs about 1½ pounds, or 29 pounds per cubic foot. The heat conductivity is state dto be approximately 12 b.t.u. per square foot per degree Fahr. difference in temperature per inch thickness per 24 hours, making the insulating value about ten times greater than ordinary red brick. The brick is composed of infusorial earth, a small amount of clay, and finely-ground cork, and has a fusing of 1,600 degrees Fahr. It is designed for insulating hot surfaces, such as boiler settings, breechings, furnaces, etc., but not being refractory, has to be protected by fire brick against excessively high temperatures. It is usually built in between two walls of regular brick or placed on the outside.

Arithmetic for the Machinist and Operative Engineer

By J. H. Rogers

Doubtless some of the elementary work in the first few articles of this series may appear more or less superfluous, but it must be remembered that numerous simple rules and formulae appear from time to time in Technical Journals, which are discarded and dubbed impractical by many operators for the simple reason that the elementals are either unknown or have been forgotten. The purpose of this course will have been achieved if the above tendency is even in part combatted.

INTRODUCTORY.

IT seems to be the unversal opinion among a great number of present-day mechanics and apprentices, that the use of figures or a general knowledge of advanced arithmetic should belong to the man higher up, the foreman, superintendent, or draughtsman.

While, to some extent, the present methods of modern manufacture, especially in large establishments, tends to eliminate from the average workman one of his greatest assets, that is, the mental faculty, which enables him to see and do things before they are actually performed, there should be no good reason why the workman, to some extent, does not become conversant with the theoretical portion of his daily labors. Some men may argue that the use of mathematics in the shop is of little importance to the average man or boy employed at the bench, on the machine, or in the power plant.

This reasoning may hold good if the man or boy has become content to remain at his present level for all time to come; but, to the ambitious person who is desirous of climbing farther up the ladder, it behoves him to fit himself to the duties of the rung above that on which he is standing. How often do we hear the remark? "He's a lucky guy," when the more reasonable view to take would be that of asking the question, "Is he a lucky guy?"

While luck or pull may have something to do with the advancement of a few, it is generally the ability of the person that secures for him the position, and his fitness that keeps him there. Few, if any, of us, would proceed very far if we were to wait and let someone push us into one of these "lucky" jobs. Although it is true, that the wheels of industry to-day are kept in motion largely by the strength and energy of men of muscle, it remains an unquestionable fact that these same wheels were first put in motion by men of brains.

Where would the steam engine of to-day be had it not been for the active mind and reasoning faculty of Watt and Stephenson?

What would the world be deprived of to-day, but for the discoveries by scientifically applied thought of such men as Franklin, Volta, Faraday, Ohm, and Ampere, and the ever-planning of Edison and Marconi?

When the identity of lightning and electricity was discovered by Benjamin Franklin, people asked, "Of what use is it?" The retort of the great philosopher was, "What is the use of a child? It may become a man." Many great revolutionary projects of to-day had apparently very insignificant beginnings, and the same may prove true of many men and boys whose only ambition seems to be to fill in the few hours that they spend in the factory.

Problems of the Daily Task.

Granting that the use of higher mathematics may be the special duty of more learned men than those usually found in the workshop, there are still many problems that the mechanic meets in his daily labors that could be more intelligently handled than at present if a general knowledge of the art of figuring was better understood by those called upon to face these questions.

Many of these shop problems, if given to the average boy just after leaving school, could be correctly solved, but the fact that the young men of to-day usually spend a year or more after leaving school before they settle their minds to the adoption of a trade leaves time enough for their brains to become rusty. Even polished steel will become oxidized if care is not taken to retain the surface of the metal.

Of what use is the knowledge we received while at school if in after life we do not take advantage of it when the occasion demands? Many workmen who are capable of solving a written question in certain lies of mathematics seem unable to grapple the same problem when met in a practical way in the shop. The study and application of calculation to practical problems in the shop exerts an influence in broadening the mind, and often keeps a person from becoming an automation or human machine.

This course of lessons in practical shop arithmetic while intended for those not conversant with the application of the principles of mathematics as applied to shop problems may also prove of some interest and help to those who to some extent are accustomed to using calculations in their daily efforts. In outlining the lessons, it will be assumed that the readers are familiar with the four elementary principles of arithmetic, namely: addition, subtraction, multiplication, and division as taught in the public schools. As far as possible the problems and solutions will deal directly with practical work, so as to appeal to the average man or boy working in machine shops, power plants, and engineering works, generally.

Throughout the course, many formulae will be necessary, but those who are not familiar with this branch of mathematics should have no scruples about using them, as they are only a short method of expressing a rule, and a little study on the part of the average man or boy will make them sufficiently proficient to understand those met with in this series of shop lessons.

Arithmetical Axioms.

Arithmetic is the art of reckoning or study of numbers.

Addition is the process of finding the sum of two or more numbers. The sign of addition is + (plus). The sign of equality is = (equals); thus, $9+2=11$ would read nine plus two equal eleven.

Subtraction is the process of finding the difference between two numbers. The sign of subtraction is − (minus); thus $40-15=25$, and reads forty minus fifteen equals twenty-five.

Multiplication is the process of multiplying one number by another, or adding one number to itself a certain number of times. The sign of multiplication is × (times or multiplied by); thus, $25\times5=125$ reads twenty-five times five equals one hundred and twenty-five. Again by addition, $25+25+25+25+25=125$.

Division is the process of finding how many times one number is contained in another. The sign of division is ÷ (divided by); thus, $42\div7=6$ reads forty-two divided by seven equals six.

Chart (1) illustrates the position and names of the various terms used.

Cancelation.

Many calculations in multiplication and division can be considerably shortened by cancelation, or the casting out of equal factors from both dividends and divisor.

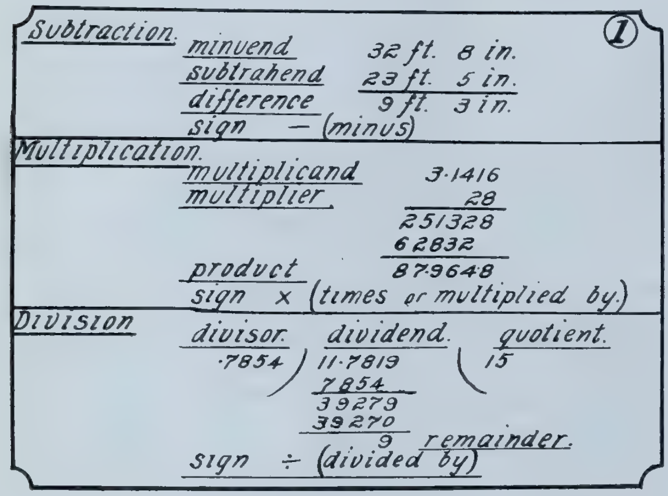
The **factors** of a number are those numbers which, when multiplied together will equal that number; thus 12 and 6 are factors of 72 since 12×6 =72.

Canceling equal factors from both divisor and dividend does not alter the quotient. Thus, dividing each term of the fraction 48/64 by 4 we get 12/16; again dividing each term by 4 we have ¾. When canceling, be sure and remove an equal factor from both terms of the fraction. Example:—

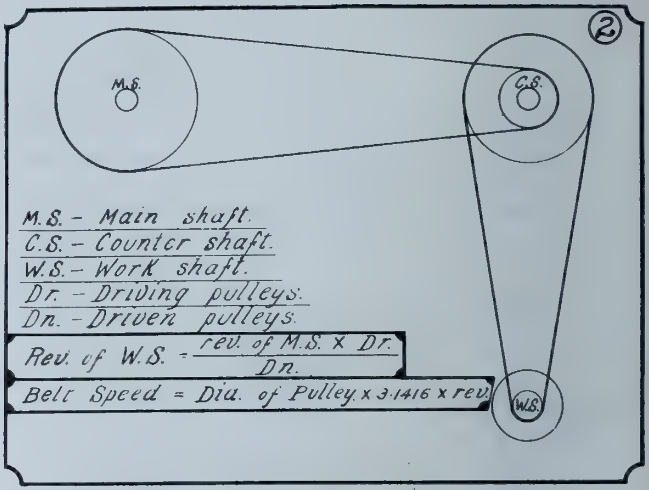
Divide 18×15×24 by 5×36.

$$\frac{\overset{1\quad 3\quad 12}{18\times15\times24}}{\underset{\substack{1\quad 2\\ \quad\;\; 1}}{5\times36}}=\frac{}{1\times1}=\frac{}{1}=36$$

Explanation:—The 5 in the divisor and the 15 in the dividend are both divisable by 5, as 5÷5=1 and 15÷5=3. Again 18÷18 = 1, and 36÷18 = 2. Further, 2÷2 = 1 and 24÷2 = 12. The cancelation being complete leaves the relation of the dividend to the divisor the same as before, but much simplified. Multiplying the remaining factors in both terms, we have 1×3×12=36 and 1×1=1; then 36÷1=36.



ARITHMETIC CHART 1.



ARITHMETIC CHART 2.

To avoid confusion, always cross out or cancel the factor affected by the process of the division. It is usual to omit the 1 when a factor is being divided by itself, as:

$$\frac{3}{6}=\frac{3}{\underset{2}{6}}=\frac{1}{2}$$

Example, see Chart 2.—An emery wheel is required to have a speed of 2,200 r.p.m. The main shaft has a speed of 185 r.p.m., and diameter of pulley on work shaft, W.S.=4 inches. Assuming we have pulleys for counter-shaft of 24 inches and 15 inches diameter, find the main-shaft.

In problems of this nature the speed of the driving shaft multiplied by the diameters of all the driving pulleys will equal the speed of the driven shaft multiplied by the diameters of all the driven pulleys, or expressed in the formula, Chart 2.

Revs. of M.S. × Dr. = revs. of W.S. ×Dn., or

$$\text{Revs. of W.S.}=\frac{\text{Revs. of M.S.}\times\text{Dr.}}{\text{Dn.}}\text{, then}$$

diameter of driving pulley on main-shaft

$$=\frac{\overset{1100\quad 3}{2200\times15\times4}}{\underset{\substack{37\quad 6\\ \quad\;\; 2}}{185\times20}}=\frac{1100}{37}=29\frac{27}{37}\text{ ins or}$$

say, a 30 in. pulley.

Fractions.

A common fraction is a certain part of a whole number.

The terms of a fraction are the numerator and the denominator.

The value of a fraction is the numerator divided by the denominator.

A fraction may be changed to higher terms of the same value by multiplying both terms by the same number; as ⅜ to twenty-four sixty-fourths. Multiplying each term by 8 we get 3×8=24, and 8×8=64, therefore ⅜=24/64.

Also, to change to lower terms having the same value, divide, if possible, each term by the same number.

To reduce a fraction to an equal fraction having a given denominator. Divide the given denominator by the denominator of the given fraction, and multiply both terms by the result. Thus ⅞ to thousandths. Then 1000÷8=125, and multiplying both terms by 125, we have 875/1000.

In addition and substraction of fractions, the fractions must be changed so they will have a common denominator. Thus, it would not be convenient to add ⅜, ¾, 7/16, 33/64 and 35/100. We must change them to fractions of the same value but with a common denominator. To accomplish this, we place the denominator in a row, thus

$$\begin{array}{ccccr|ll} 8 & \quad 4 & \quad 16 & \quad & 2 & 64 & \quad 100\\ \cline{6-7} & & & & 2 & 32 & \quad 50\\ \cline{6-7} & & & & & 16 & \quad 25 \end{array}$$

If any of these numbers are contained equally in one or more of the others, it may be eliminated. thus, four goes into 8, therefore, cancel 4. Eight goes into 16, therefore, cancel 8; sixteen goes into 64, therefore cancel 16. This leaves 64 and 100. Now, 64 will not go into 100; but we see that there are still factors of both numbers that are common to each other. To eliminate these, we proceed as follows:—Divide both numbers by a prime number; in this case 2. We get 32 and 50: Again, dividing by 2 we get 16 and 25. Now, these numbers, 2, 2, 16 and 25 when multiplied together will give what is known as the Least Common Denominator.

Addition of Fractions.

When changing to fractions having the least common denominator, write the sum of all the numerators over the common denominator, and, if necessary, change to a mixed number.

Subtraction of fractions.

When changing fractions to other fractions having a common denominator, subtract the numerators as is done in whole numbers and place the difference over the common denominator.

Multiplication of Fractions.

In multiplication of fractions, it is not necessary to use a common denominator. Divide the product of the numerator by the product of the denominators. All factors common to both terms should first be cast out by cancelation. When mixed numbers are involved, first change them to improper fractions; and if the answer is an improper fraction, change to a mixed number.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the accompanying course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

Question.—Give a definition of the mechanism as expressed by the word **Turbine.**

Answer.—A turbine is a prime mover in which gradual changes in the momentum of a fluid are utilized to produce rotation of the moving members.

* * *

Question.—Explain the difference between a turbine as above described and a rotary engine.

Answer.—In order to fulfil the requirements embodied in the answer to the first question, the only method suitable in practice for communicating the fluid energy to the rotor parts is to occasion a change in the fluid velocity. It should, therefore, be noted that pressure plays no part in the operation. A rotary engine on the other hand depends for its action on pressure, and in consequence is a mechanism entirely distinct from the turbine.

* * *

Question.—What is understood by the **Load Factor** in an electrical installation?

Answer.—The load factor of an electrical power plant or any unit of it is the ratio of the average output to the maximum. Thus, if, in an electrical installation, M=the maximum kilowatt output, and K=the total output in N hours, then the load factor for that period is $\frac{K}{M \times N}$. As this is commonly expressed as a percentage, the load factor $=\frac{K \times 100}{M \times N}$. The period usually taken is one year, therefore the load factor=

$$\frac{\text{Total Units Generated} \times 100}{\text{Maximum Load} \times 24 \times 365}$$

* * *

Question.—What do we understand by the expression, **Total Heat of Steam?**

Answer.—By the total heat of saturated or boiler steam is meant the number of heat units required to produce one pound of steam from a temperature of 32 degrees Fah. to any given temperature and pressure. The total heat includes the latent heat of steam formation and the sensible or thermometer heat.

* * *

Question.—What is understood by the term **Horse Power** as applied to steam boilers?

Answer.—Horse power when used with reference to steam boilers means the capacity to evaporate 30 pounds of water per hour from a temperature of 100 degrees Fah. into steam at 70 pounds gauge pressure, or 34½ pounds of water evaporated per hour from a feed water temperature of 212 degrees Fah. with steam at atmospheric pressure. This unit of power is that adopted by the American Society of Mechanical Engineers and generally accepted on this continent as a standard.

* * *

Question—What steps should be taken previous to putting a new boiler into operation, so as to ensure that the internal surfaces are thoroughly clean?

Answer—Before putting a new boiler into operation, it should first be well boiled-out for at least 24 hours with a strong solution of compound, using the surface and bottom blow-off for about two minutes each hour; feeding with distilled water, if possible, to make up the loss, and adding more compound after each blowing-off. Again, before starting the use of compound in an old boiler, the same preliminary details should have attention; the reasons for their adoption being as follows:—

(1)—When starting-up a new battery of boilers, there is always found more or less greasy scale and dirt thrown down, even when good distilled water is used for boiler feed.

(2)—In an old boiler which is considered to be as clean as possible, a good compound will cut a very considerable amount of grease and scale from the apparently clean surfaces.

(3)—In an old boiler which has not been cleaned, the action of the compound would first be to form colloidal solutions with any scale-forming ingredients that are in the water. The excess of compound then acts on the scale and grease attached to the various surfaces, loosening and throwing them down on to lower surfaces, and in time dissolving these impurities. If the boiler be boiled out, using good water with the compound, much of this scale and grease will be loosened and a great part of it can be removed through the blow-off. After boiling and blowing for 24 hours, the fires should be allowed to die out, and before the pressure is entirely gone, all the water should be blown out. The lower manhole and handhole plates should then be taken off and all loose scale raked out. If this is not done the loose scale and greasy solution may do the boiler harm.

Question—What is the generally accepted meaning of the expression, **Isolated Plant**, as applied to a power station?

Answer—An isolated plant is one which produces power by means of prime movers, the method of application being immaterial. The plant is isolated from the central station, and, in the broad sense of the word, a small central station in territory supplied by a large central station would be classed as an isolated plant.

* * *

Question—What are the usual arrangements of Corliss valve gears in steam engine practice?

Answer—Gears without trip motion, the valves having a positive connection with the eccentric, the travel constant, and the point of cut-off invariable. This arrangement is not, however, much used.

Single eccentric gears with trip motion in which the steam valves are not positively connected to the eccentric, but are opened by trips or catches against the resistance of a dash-pot, and released at some point of the engine stroke, determined by the governor or otherwise. The exhaust valves are positively connected to the eccentric and receive therefore a constant movement.

Double eccentric gears with trip motion in which the steam valves are connected and operated in the same manner as those of the single eccentric with trip gear. The exhaust valves are, however, driven from a separate eccentric.

* * *

Question—What is Boyle's Law?

Answer—Boyle's Law defines a perfect gas as having a constant pressure volume.

$$pv=\text{constant}.$$

Example—Steam at 100 pounds pressure in a vessel of 10 cubic feet capacity.

$$100 \times 10=1000.$$

If we pass that steam into another vessel which is 20 cubic feet capacity, the pressure will fall to 50 pounds, thus:

$$\frac{1,000}{20}=50 \text{ pounds},$$

showing that the constant value remains the same. It is this volume increase, that calls for ports and exhaust pipes being larger in area than live steam admission openings and live steam pipes; the pressure being lower.

ASSOCIATION AND PERSONAL

A Monthly Record of Current Association News and of Individuals Who Have Been More or Less Prominent in the Power Field.

Colonel Ruttan, Winnipeg city engineer, addressed the University of Manitoba Engineering Society, two weeks ago.

A. J. MacLean, a former commissioner, assumed the duties of Assistant City Engineer of Edmonton, Alta., on February 2.

D. W. Johnson, for the past five years municipal engineer of Point Grey, B.C., has resigned, having accepted a similar appointment at Saanich, B.C.

J. W. W. Drysdale, Jr., B.Sc., director of Drysdale and Co., Glasgow, Scotland, manufacturers of centrifugal pumps is in Canada on a brief business trip.

M. J. Butler was elected president of the Canadian Society of Civil Engineers at their twenty-eighth annual meeting held in Montreal recently.

Professor Herdt, of McGill University, and R. S. Kelsch, consulting engineer, Montreal, are inquiring into the cost of power as furnished the City of Fort William by the Kaministiqua Power Co.

A. D. Stephens, chief engineer of Dominion No. 1 Colliery, Cape Breton, who has been on the sick list the past three weeks is now rapidly recovering, and will be about his accustomed duties in a week or two.

F. Ross Newman, resident manager in Toronto of the Canadian Fairbanks-Morse Co., sailed from New York on Saturday for Europe, where he will spend a short holiday. During his absence George E. Fisher is in charge.

Engineers' Club, Toronto.—At the annual meeting of the Board of Directors of the Toronto Engineers' Club, the following were elected officers for the coming year:—President, Col. A. Van Nostrand; 1st Vice-President, Charles H. Hays; 2nd Vice-President, Wm. A. Bucke; 3rd Vice-President, Edward L. Cousins.

T. J. Brown, general superintendent of the Nova Scotia Steel & Coal Co., and Vincent McFadden, chief electrician of the Dominion Coal Co., Glace Bay, N.S., are members of a commission appointed by the Nova Scotia Government to inquire into the advantages or otherwise of electricity for light, heat and power in coal mines. The commission visited Sydney recently.

BRITISH COLUMBIA ASSOCIATION OF STATIONARY ENGINEERS.

Treasurer—W. E. Archer, Hamilton.

Doorkeeper..E. Hooey, Owen Sound, Ont.

Conductor—Robert Dyson, Guelph, Ont.

Economy Pumping Machinery, is the title of a new catalogue which has been issued by Thomas & Smith, Chicago. The catalogue deals fully with the "Economy" line of pumps which includes centrifugal, bilge and deep well pumps, sewage ejectors, etc., motor or belt driven. Each type is illustrated and described together with a table giving principal sizes and ratings. In many cases a specification is included. The catalogue also contains some suggestive specifications and several pages of useful information on pumps and hydraulics, which will be helpful when considering pumping propositions.

Canada Metal Co., Convention.—The Annual Convention of the managers and sales staff of the Canada Metal Co. was held at the head office, Toronto, recently, when managers were present from the Montreal and Winnipeg offices, and salesmen were gathered from all parts of the Dominion. At the opening function, W. G. Harris, Jr., vice-president, stated what a pleasure it was once more to meet their representatives in Toronto. In a concise manner he dealt with the objects of the Convention. Amongst these was the exchange of ideas on trade conditions throughout the Dominion, which would prove rich in information, also the great benefit derived by general discussion. The president, W. G. Harris, Sr., also had a word of welcome and spoke of the strenuous year just past. He stated that it was a year of which every one in connection with the Canada Metal Co. had just reason to be proud, for it was the best and most progressive year in the history of the company. Many interesting papers were read by the various salesmen upon a diversity of subjects.

SIEMENS

SIEMENS

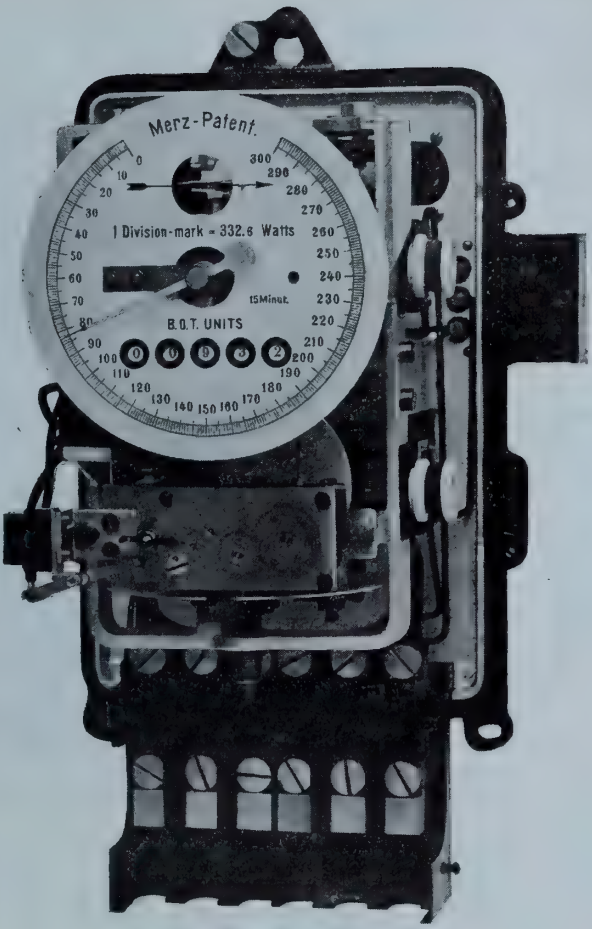
SIEMENS

SIEMENS - SCHUCKERT | SIEMENS & HALSKE

What the Meter does

1. Gives the kilowatt hours.
2. The highest load demanded in watts on a time average of say 15, 30 or 60 minutes.

The accurate measurement of these two quantities enables a true load factor system of charging to be adopted.



What can be done with the Meter

1. Charge an annual sum per K.W. year or Horse power year to cover capital and standing costs.
2. Charge a low straight rate per K.W. hour based on running costs and profit required.

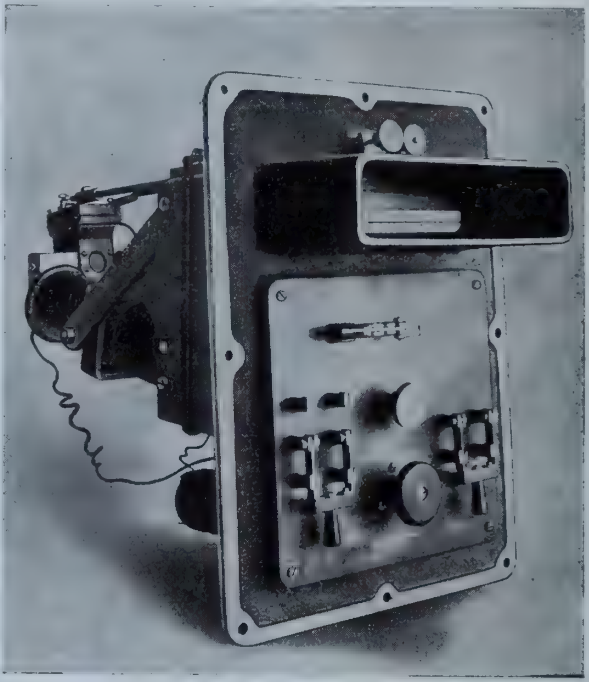
PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

NEW TYPE VOLTMETER.

IN the testing of insulated wires and cables designed for a great variety of purposes, a voltmeter as we have known it heretofore, often fails to measure adequately the stresses to which the dielectric is subjected. Based on the integration of the sine wave—on the square root of the mean square of instantaneous values — voltmeter readings give little or no indication of unusual peaks in the voltage wave or of surges in the circuit.

The need of an instrument which would give such readings arose in connection with the high voltage testing of wires and cables, it being well-known that, in such tests, the peak of the wave is what counts in breaking down the insulation. So long as a sine wave is maintained, the ordinary voltmeter indicates the peak voltage—a definite percentage above the voltmeter reading, but in cable testing, there is a considerable charging current, due to the electro-static capacity of the cable. As this current is likely to distort the wave form, the ordinary voltmeter may give no definite information as to peak voltage.



FRONT VIEW—SIMPLEX PEAK VOLTAGE METER SHOWING CONTROL BOARD AND SCALE.

After trying and discarding both a spark gap, which proved to be too easily affected by outside conditions, and an oscillograph, which is too delicate an instrument for factory use, the engineers of the Simplex Wire & Cable Co., Boston, proceeded to develop for their own use apparatus which would give the required results. Based upon the principle of the oscillograph, but with its movement confined to a straight line, the new instrument, illustrated herewith, indicates the peak of the voltage wave at the limit of oscillation along that line. It does not show the character of the wave or the form of its peak, but it

GENERAL CONSTRUCTION OF NEW METER.

Does what
we claim

WARRANTY

We guarantee **PEROLIN** the German Boiler Metal Treatment.

1. To remove scale already formed in your boilers.
2. To prevent new scale from forming.
3. To stop all pitting, corroding and galvanic action.
4. Not to corrode or injure the boiler metal or packing.
5. Not to affect or impart any off-odor to steam generated from the water.
6. To correct oil troubles caused by oil or grease getting into boiler water.
7. Not to affect the product of Breweries, Ice Plants, Creameries, Dye Works, or any Product where live steam is used in the manufacture of their goods.
8. That it does not affect the water, neither is it affected by the water, and that the Perolin Preservative Film is a good transmitter of heat.

PEROLIN does not treat the water.

PEROLIN **preserves** the Boiler Metal, and we guarantee the Perolin Preservative Film to be a good transmitter of heat.

PEROLIN will prove just as agreeably effective in your boilers as in others'. We stand ready to demonstrate it at **our** expense — **no cure, no pay.**

Will you write us to-day for further particulars?

Perolin Co of Canada. Sep 1st 1913

Dear Sirs

With reference to the use of your Boiler Compound in our Boilers, we have used it as directed & have found it to be all that you claimed for it & more. when we started using it there was a Scale on the Tubes & Tubesheet ranging in thickness from 1/16" to 1/4" thick but now they are nearly all clean & free from Scale what is left on is quite loose & comes of quite easily, we had all three Boilers opened up two weeks ago & the Boiler Inspector was inside them with me and he remarked how clean the Boilers were this year & asked me if I was using Perolin & he says he hears wherever it is used it does good work. & I can honestly Say it is the first Compound I have ever used to give Satisfaction

Wishing you Success

Iam your Truly
Chas. R. Watson. Engineer Russell Motor Car Co.

does give very clearly the reading for that peak, whatever the shape of the wave may be. This peak voltage meter, in its original crude state was used successfully in the Simplex factory for some time, and thus thoroughly tested out. It has just been completed in its present form, after an experimental period extending over two years.

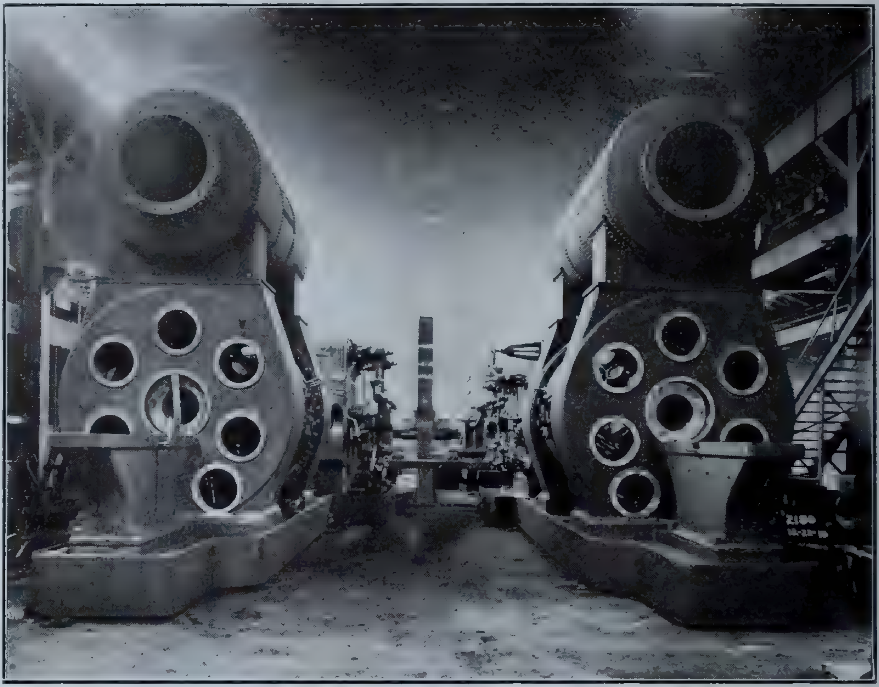
The voltmeter, which is of switchboard type, measures about 10 by 12 in. on the front and 14 in. deep. It consists essentially of a heavy electromagnet, between the poles of which is located the vibrator. By a suitable arrangement of lamp, mirror and lenses, a beam of light is thrown on a ground glass scale in front, graduated in volts. This instrument is connected, through a potential transformer, directly on the high voltage circuit, the current being so small that the apparatus can be left in the circuit all the time. It can be quickly calibrated at any time by applying direct current of known voltage.

This interesting example of the development of an invention to meet a particular factory need might prove of considerable value in other lines as well as that of the manufacture of insulated wires and cables, but its principal indication is the readiness of the American manufacturer to undertake both the deep study and the careful experimental work needed to provide him with the tools with which his regular work can be carried on to best advantage.

◆

RECORD IN BUILDING LARGE ENGINES.

WHAT is believed to be the world's record in constructing engines was recently accomplished by the Mesta Machine Co., of Pittsburg, Pa., in building two horizontal cross compound blowing engines for the Woodward Iron Co., Woodward, Ala. The first engine was completed and loaded on board cars at the Mesta Works in 38 days, and the second one in 59 days from the date of signing the contract at Woodward, Alta. Each of these engines embraces one high pressure steam cylinder, 48 inches in diameter, one low pressure steam cylinder 84 inches in diameter, and two air cylinders 84 inches in diameter, with a stroke of 60 inches.

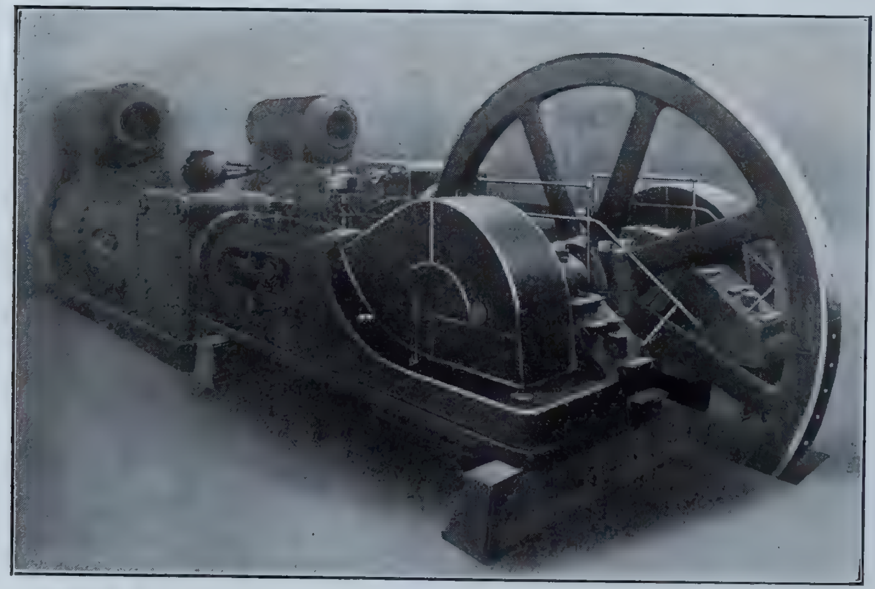


AIR RECEIVERS AND AIR CYLINDER ENDS 48-84-84 IN. X 60 IN. CROSS COMPOUND BLOWING ENGINE.

The Woodward Iron Co. had installed two large turbo blowers to furnish blast for their new 500-ton furnace, recently completed. These blowers were in operation for about a week, only, when both were wrecked. It was then decided to replace them by reciprocating steam engines. After investigating different types, they decided on horizontal cross compound steam engines. Quick delivery was of course all important.

The Mesta Machine Co. offered their new type of horizontal cross compound blowing engine, equipped with the Iversen patent automatic plate valves, and agreed to deliver the first engine on board cars at the Mesta Works in 90 days and the second engine in 120 days. On November 15, 1913, a contract was signed for two of these engines, with delivery as stated above, a bonus and penalty clause being included.

The magnitude of the task is better realized by a statement showing the work handled. The engines weigh 1,800.000 lbs., and contain 10,210 pieces. The lightest piece weighs one-fourth of an ounce, the heaviest piece 94,550 lbs.



48-84-84 IN. X 60 IN. CROSS COMPOUND BLOWING ENGINE ON ERECTING FLOOR.

Description of the Engines.

The engines are of the horizontal cross compound type, with the air cylinders placed directly back of the steam cylinders. Both the high and low pressure steam cylinders are equipped with Corliss valve gear and the air end with Mesta (Iversen Patent) automatic inlet and outlet valves. These valves require no valve gear, and allow the air cylinders to be placed directly back of the steam cylinders. This same arrangement is used also in the design of Mesta gas driven blowing engines. A large receiver is placed over the air cylinders, which practically eliminates vibration in the air lines to the furnace. The engines are designed for 30 lbs. air pressure and to run at a speed of 80 r.p.m.

KEEP YOUR EYE ON THE COAL PILE

If your coal bills are gradually increasing without a corresponding increase of power, there is a reason for it, and it is a safe bet that the increase is caused by scale in your boilers. And if you have scale, the logical thing for you to do is to order a LIBERTY TUBE CLEANER and stop the useless waste.

A LIBERTY CLEANER will pay for itself many times over, and there is no other investment you can make that will pay as large a dividend for the amount invested. Think it over.

We will send you a Liberty Cleaner on trial. If it fails to do your work *better* than any other make of Cleaner, you don't have to keep it.

"TWINS" EXCITE ADMIRATION

Because They Earn It

Think of a TWIN when you hear the word STRAINER

The installation of a Twin Strainer on your water supply line eliminates troubles, worry, waste of time and expense—because

It has two straining baskets—that may be cleaned alternately, thus permitting continuous operation.

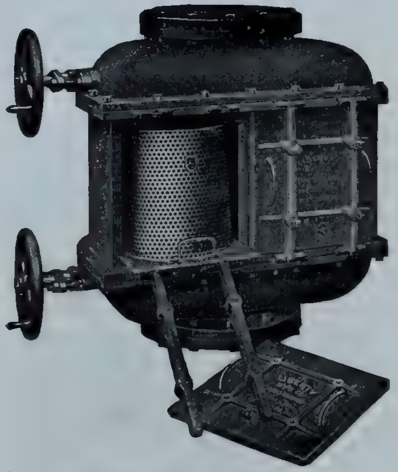
It has but two valves—they are of the gate type and are always tight.

It gives a direct flow with minimum friction loss, insuring easy operation with no waste of energy.

In fact, a Twin Strainer is an insurance policy in active service.

Designed to protect and built to last.

Write for our bulletin.



THE TWIN STRAINER.

POWER PLANT DEVELOPMENTS

A record of current municipal, manufacturing and general industrial projects, involving steam, gas, oil, electricity, air and water power equipment requirements.

Electrical

Collingwood, Ont.—The Imperial Wire and Steel Co. have made a contract for 350-h.p. Hydro-Electric power, to be supplied some time this month. Another 100 h.p. will be necessary for a new addition shortly to be erected.

Maisonneuve, Que.—The shipbuilding plant of the Canadian Vickers, Ltd., will be driven by electrical motors, constructed in England by Vickers, Ltd. Current at 10,000 volts will be supplied by the Montreal Light, Heat & Power Company.

Fredericton, N.B.—F. W. Barbour, consulting engineer, Boston, has advised the council not to accept the proposition of the Eel River Light, Heat and Power Co. to furnish power to operate the pumping station. He recommended certain changes in the pumping station and filtration plant.

Longueuil, Que. — The Armstrong, Whitworth Co., of Canada, who are building a plant at Longueuil, Que., propose to install a power and lighting plant. Current will be supplied by the Montreal Light, Heat & Power Co., at 22,500 volts, which will be transformed to 2,200 volts.

Ottawa, Ont.—W. S. Edwards & Co., Sussex St., are applying to the Government to have their charter amended so that they may manufacture electricity for heat, light and power purposes. Power will be developed on the Rideau River at Rideau Twin Falls.

Nanaimo, B.C.—The Nanaimo Electric Light and Power Co. have installed a direct connected 450 h.p. unit, supplied by James Howden & Co., Glasgow. The generator was the product of the Bruce, Peebles & Co., Edinburgh. There was also installed a six-panel switchboard, a Stillwell heater, and a Worthington feed pump. Further equipment will be required for a service to South Nanaimo.

Cobalt, Ont.—Last week, acting under instructions from M. J. O'Brien, mine-owner and contractor, Sutcliffe & Neelands, civil engineers, of New Liskeard, put men at work to get information concerning the possibility of developing the water-power on the Quinze River, near the head of Lake Timiskaming. Mr. Neelands believes that the Quinze River has power enough to develop 270,000 horse-power, and thinks this would be sufficient to electrify the T. & N. O. R. and supply heat, power and light for all the industries of Timiskaming.

Kingston, Ont. — The Napanee River Improvement Co. has made a power offer to the Utilities Commission of Kingston. It owns property at Third Lake Depot, 35 miles from the latter city, where there are falls with a 65-foot drop, with at least 1,000 horse-power for the whole year, and 2,000 horse-power for eight months available. This power could be brought to Kingston at an expenditure of about $50,000.

Municipal

New Toronto, Ont.—If the ratepayers approve, $27,000 will be spent to provide a water and filtration system.

Lethbridge, Alta.—It is likely the capital estimates to be tabled by Commissioner Grace will contain an appropriation of about $15,000 for the installation of meters on all water connections in the city.

Winnipeg, Man.—City Engineer Ruttan has recommended to the fire, water, light and power committee that the steel pipe which now extends from well 10 to near well 28 be continued to a point close to Popular Springs, a distance of 25,080 feet.

Ottawa, Ont.—Judge Latchford on Feb. 7, granted an injunction against the city's proceeding further with Sir Alex Binnie's scheme to bring water from the Gatineau Lakes. The by-law had already been quashed by Mr. Justice Lennox, but the Board of Control on February 3rd opened tenders for the pipe line contract. The latest injunction declares the scheme illegal, and prevents the award of contracts, pending trial of the injunction.

Sydney, N.S.—The city is in the market for a new motor fire engine, and a fire alarm system. The storage battery system which is recommended and upon which the electrician will report in due course is with its cost as follows: 105 storage battery B. T. couples complete with electrolyte; 1-60-inch double battery rack; 1 Northern electric 4 circuit storage battery switch board; 1 one-h.p. alternating current single phase 60 cycle 110 volt motor mounted on common sub-base direct-connected to 5 ampere direct current generator.

Sudbury, Ont.—A scheme to provide the towns of Copper Cliff and Frood Mines with a pure water supply at a cost of $200,000, and provide for a population of 17,000, has been planned. The work of construction will commence without delay. The Canadian Copper Co. will finance the work. A high-pressure pumping station and a 100,000 gallon storage tank in Copper Cliff of reinforced concrete is part of the scheme.

Hamilton, Ont.—City Engineer MaCallum has submitted an exhaustive report on the city waterworks system. The secretary of the Underwriters' Association, recently recommended going back to steam power for pumping and other changes. Mr. MaCallum thinks that the city should have a duplicate pumping plant, as it now has a duplicate system of pipes. He also suggests as an alternative that the city take power from the Cataract Company and have devices for using either Hydro or Cataract power. The additional steam plant will cost $65,000.

Sydney, N.S. — Work will be commenced at once to connect Middle and Dumeresq Lakes with the city water supply. The city council will call tenders for 11,000 feet of twenty-four-inch pipe and for the clearing of a road and pipe line right-of-way to the lakes. The storage capacity of Middle Lake is estimated at 191,500,000 gallons which would it is believed, maintain a daily supply of about 6,000,000 gallons in addition to the present rate of consumption. The engineer recommends the installation of centrifugal pumps; two units of 3,000,000 capacity each, to be either operated by electric motor or oil engine. The total estimated cost is $87,000.

Boiler Preservative

acts on the iron—not on the water. It is a boiler treatment in a class by itself.

Water treatments are only partially successful, because the scale-forming sediment in water changes with seasons, climates and localities.

"MAGIC" removes scale and oil first, and then prevents scale forming. It stops pitting, corrosion and minor leaks.

"MAGIC" saves the boiler and much labor.

A trial will convince you—write us.

You're never cornered with a

Starrett Patent Ratchet Wrench

It will turn any standard nut or bolt in all sorts of difficult places—places where the ordinary monkey wrench is useless. The ratchet permits rapid action with only a short arc swing. The extension reaches into otherwise inaccessible places. The drilling attachment furnished with the wrench takes any twist drill from 1/8 in. to 1/2 in. A reversible screw driver makes it handy for turning screws of various sizes, too. Send for catalog No. 20CD, and see the whole Starrett line of fine tools. It's worth while.

No Work on Sundays—

and less work the week through; boilers that steam better—and less kicks from the boss about the coal bill.

These are some of the things that happen after you have let

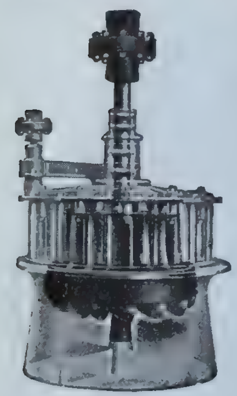
WALKER'S ELECTRIC BOILER COMPOUND

rid your boilers of scale and keep them clean. Fed in with feed-water it will accomplish this —rapidly—thoroughly, and without harming your equipment in any way.

And remember our big line of Steam Users' Supplies is worth investigating.

May we send prices?

The Electric Boiler Compound
COMPANY, LIMITED
Guelph, Ontario



For All Water Power Purposes

If you have a water power you can use, the "Samson" wheel will develop that power most economically.

The high efficiency shown by this wheel in official tests proves its economy in the use of water, and shows what the wheel will do for you when working under your conditions.

It is easily installed, and when in operation is easily controlled.

The "Samson" is always sold on an absolute guarantee.

The Detroit "500" will not syphon

The Detroit "500" Air Compressor Lubricator gives constant lubrication under every condition of service. The rate of feed never varies when changing from pressure to unloading or when returning from unloading to pressure.

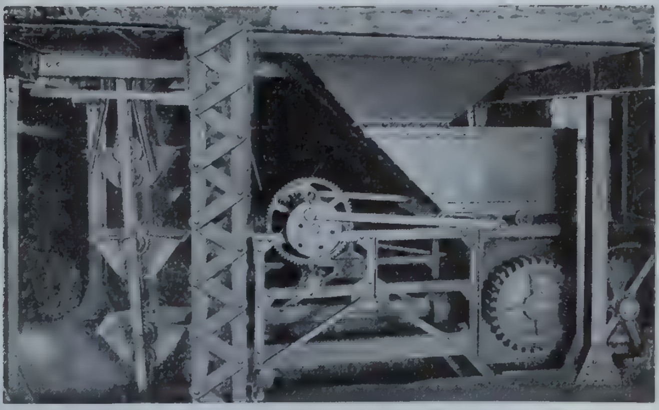
The Detroit "500" cannot be robbed of oil and cannot be affected by changing conditions in the cylinder.

This lubricator can be started and stopped without changing the feed adjustment, preventing both loss of time and oil when starting up.

The bullseye gauge and sight feed glasses are kept tight and won't break. This lubricator will withstand the roughest service.

CANADIAN DETROIT LUBRICATOR COMPANY, LTD.

WALKERVILLE, ONTARIO



Power Plant Costs are being lowered at this plant with

Jeffrey Coal and Ashes Handling Machinery

The coal is dumped into the receiving hopper in the basement. Plate Feeder with adjustable stroke delivers slack coal direct to buckets or lump coal through crusher to buckets, which deposit it in overhead bunkers.

Our New Catalog 32-B, just off the press, gives details of other interesting installations. Write for Copy.

JEFFREY MANUFACTURING COMPANY

Canadian Main Office and Works, MONTREAL

There Are Over 800 Otis Heaters in Buffalo Alone

Throughout the various states, thousands upon thousands of horse-power are in use.

Why this popularity?

Because Otis Heaters occupy a place in the engineering world that is second to none.

It is the only pressure heater made that contains an effective oil separator and cool settling chamber.

The exhaust is the heating agent, and 212° is the ordinary, not the spasmodic, temperature of the water.

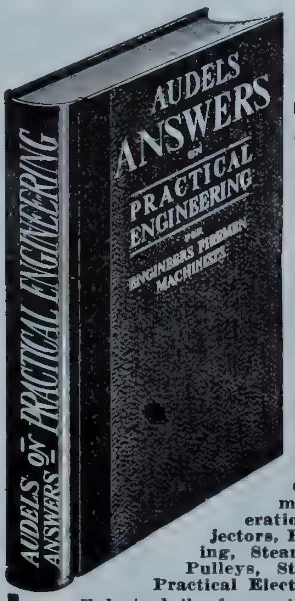
The Otis has unusually large capacity and heating surface, and is tested under 200 lbs. hydrostatic pressure.

There's a "rock-ribbed" guarantee that covers every function and part of the Otis Heater.

Try it for 30 days at our expense. You have nothing to lose, and much to gain.

Catalog on request.

Stewart Heater Company
189 Norfolk Ave., Buffalo, N.Y.



ENGINEERS

THIS book deals largely with the foundation principles which govern the practice of steam engineering. Nothing so soon condemns the applicant as want of knowledge of the every day practice and simple laws relating to the care and management of a steam plant.

No one is expected to know everything, but all are required to be familiar with certain facts which may be called "the beginning of things."

The lack of knowledge of the small things carries conviction of the same lack in the larger.

Plain facts, that you should know, are plainly explained in AUDELS ANSWERS ON PRACTICAL ENGINEERING, answers your questions on

Air, Water, Steam, Fuel and Heat, Steam Boilers, Boiler Construction, Water Tube Boilers, The Steam Gauge, The Safety Valve, Properties of Steam, Installation of Boilers, Management of Boilers, Engineers' Law, Firemen's Law, Steam Engines, The Valve and Valve Gear, The Corliss Engine, Engine Arithmetic, Lubricators, Installation and Operation of Engines, Steam Pumps, Injectors, Feed Water Heaters, Steam Heating, Steam Traps, Belts, Gears and Pulleys, Steam Turbines, Refrigeration, Practical Electricity, Elevators.

Understand the framework of which your work is but a cross bar. Know something of the cause of which your work is but an effect. Know something of the effect of which your work is the cause. And, above all, know why it is done one way and not another.

LEARN THE THEORY UNDERLYING THE WORK

PRACTICAL ENGINEERING contains 288 pages fully illustrated, handsomely bound and printed, and is in every way a first-class book.

FREE (No Duty)
EXAMINATION

Sign and mail the coupon, and it will bring to your plant a book of sterling merit, for free examination. You can have one week in which to dig out valuable information contained in its 200 or more pages.

THEO. AUDEL & CO., 72 5th Ave., NEW YORK

Feed Without Pumps!

Drain *all* steam-heated surfaces in your plant of *all* condensation. Keep every inch of it dry and active. Return your condensation directly *back to the boiler* without use of steam pump or injector, and without loss of heat units contained in excess of 210 degrees— turn it into dry, hot steam, ready for *re-use.* Do all this automatically, wastelessly.

Replace every boiler feed pump in your plant with the Morehead "Back to Boiler" System. Save coal, save water—give your boiler the benefit of a large percentage of pure feed water at the highest possible temperature.

Morehead
Back to Boiler
SYSTEM

No more loss of radiating surface—no more condensation waste—no more pump troubles—

Install the "Morehead"!

Get the Catalog

Every Engineer should have it. Tells all about the handling of condensation and the Morehead "Back to Boiler" System. Very interesting.

Write for it

The operation of the Morehead System is exceedingly simple. When the drum fills with condensation, live steam is admitted to force out the water—into the boiler. No inconvenient stuffing boxes—no leaky valves—no expensive breakdowns of pumps or old-style valves. Simply installed.

Put a Morehead Trap in your plant on 30 days' trial. Write the Condensation Department for Catalog and Records of Savings and Results Obtained From Their Use.

Canadian Morehead Mfg. Co., Ltd.
WOODSTOCK, ONTARIO

WHY USE OIL

When GREASE
Gives More
Uniform Lubrication, Is Better and
Much Cheaper?

This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

Write for particulars.

RETURN STEAM TRAP FOR FEEDING BACK HOT

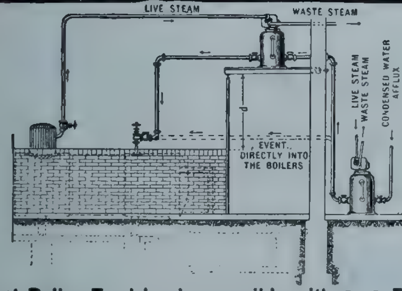
Founded A. in 1878
Export

GREAT SAVING IN COALS AND WORKING EXPENSES.
INCREASED BOILER EFFICIENCY.
INCREASED LIFE OF BOILER.
MINIMUM OF BOILER INCRUSTATION.

SCHNEIDER & HELMECKE-MAGDEBURG
Special Works for Steam Traps

CONDENSED WATER DIRECT TO BOILER, WITHOUT PUMP.

THE MOST RATIONAL



SELF-ACTING BOILER FEED

Direct Boiler Feed is also possible with **one** Return Steam Trap according to the situation.

Dominion Sugar Company, Ltd. We received your favour of the 5th inst. and noted its contents. To our great satisfaction we are able to inform you that your Return Steam Traps, are working excellently. We have now installed all four, which have worked faultlessly right away from the commencement. — One double Return Steam Trap suffices for conveying the condensed water from 6 Sperber drying apparatus directly back to the boilers. — *Since the Return Steam Traps were installed the feed pump for the boilers of the splitting-drying department has not been used.* — The saving in coals is considerable, since by aid of the Return Steam Traps we can now easily keep up full steam, whereas previously we had constantly to force the boilers to the utmost. After the experience gained with your condensed water Return Steam Traps we must admit, that no plant ought to be without the same. The feed pump has always been a unisance to us.
We leave it to your discretion to make whatever use of this you please.
Wallaceburg (Canada), Ont., Novbr. 22 nd, 1909.

BOILER FEED WATER TROUBLES

Corrosion, Pitting, Foaming, Scale Formation, due to the mineral elements in the water—cannot be overcome by any "Cure-all" method.

Definite knowledge of the nature of the water,—obtained by analysis,—is essential in setting about to correct these conditions. The proper reagents must be provided in the treatment to counteract the injurious minerals found in the water, and reagents must be used that will not form in combination by-products that will prove injurious to the boiler metal.

Dearborn Treatment

is prepared according to these scientific principles,—and the desired action is assured. **Your inquiry will have our immediate attention.**

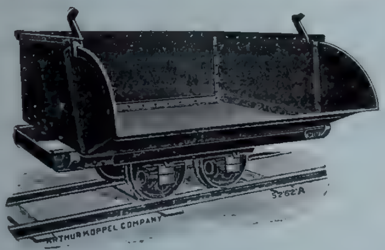
- Recording Instruments for All Purposes

Write us regarding your requirements.

Union Trust Building, - - Winnipeg, Man.



A VERY satisfactory type of car for use in hauling ashes, dirt, etc., is the Scoop Car, which can be dumped either between the rails or to either side. Standard capacities are 12, 18 or 27 cubic feet for gauges of 18 or 24 inches.

How to Charge Furnaces Economically

A very important factor in the problem of keeping a constant supply of power is that of how to stoke furnaces efficiently. We are selling agents for a system of conveying coal and for charging furnaces in boiler rooms which requires very little labor and is practically indestructible. This system consists of the well known Koppel Cast Plate Track and Charging Cars.

ORENSTEIN-ARTHUR KOPPEL

Coal Charging Cars for the conveying of coal to boiler rooms are made of steel and are very durable. They are light in weight and easy and convenient to operate, being designed with special reference to boiler room service. The height of the cars is such as to make shoveling very convenient for the stoker. They may be supplied either with two side doors or end doors, as desired, and with or without swiveling base.

The rails of the track used in our boiler room systems are cast integrally with solid sectional plates, which provide a level surface to walk upon while car is being propelled.

We have a very interesting catalogue on this subject, showing many installations of the Koppel System, together with illustrations of cars, track, switches, turntables, etc., which we should like to send you. Ask for catalogue 412.

Round edge hard drawn copper.

Every link stamped with name "Economy" and capacity. Guaranteed to operate as marked.

This venting feature allows no fire to escape, even on severe short circuits.

Washer assembly centres, locks in position and aligns blades.

Heavy solid brass cap.

Unusually heavy gray horn fiber shell.

Short, active length of element assures uniform performance.

Links are attached to blade member by heavy machine screws.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are **reducing fuse Maintenance expense over 80 per cent. by using**

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

Write for Bulletin, Prices and Discounts

Economy Fuse & Mfg. Co. of Canada, Limited

Herald Building, Montreal

ECONOMY Renewable Fuses are sanctioned by the Canadian Fire Underwriters' Association.

PRACTICAL BOOKS FOR PRACTICAL MEN

These books were written especially for practical self-instruction, by experts whose experience and standing make them authorities.

They are so clear that the beginner can understand them; so thorough that the trained worker can learn from them; so practical that they will give any man a working knowledge of the subjects that they treat, and save him both time and money.

They not only cover the fundamental principles of mechanical science, engineering practice, and business usage, but also present the latest developments and the accepted practice of the most successful men, in those lines.

They give men a practical knowledge of practical things, which enables them to think more accurately and to work more efficiently; and they compose the most helpful, reliable, and comprehensive series of **home study** books ever put upon the market.

The advertiser would like to know where you saw his advertisement—tell him.

Put this valve on your steam line and forget about the pressure.

Davis Pressure Regulators Save Steam

Besides the economy of the thing, there is much satisfaction in being able to get any pressure you want in your plant regardless of the boiler pressure.

No matter what the operating conditions may be, if the result you want to get is a lower pressure for a given purpose, you have at your command the

DAVIS Pressure Regulator

This automatic valve may be set for any delivery. Fluctuations in the high pressure do not affect its action, and it is good for years of service because it is very simple in construction.

All Davis Pressure Regulators are sold on approval at our risk. They must satisfy you fully or there is no sale. Let us have your inquiries.

Made in all sizes from ½ to 14-inch, with either screwed or flanged ends.

PENBERTHY
MARK

Automatic Cellar Drainer

A water pressure ejector of high capacity, automatically operated by a float-controlled, quick-opening and closing valve.

Adapted For Use In

Pits, sumps, cellars, tanks, settling basins, elevator or other pits located below the sewer level or wherever it is desired to keep water or other liquids from rising above a certain level.

SOME ADVANTAGES OVER OTHER MAKES:

All parts, except the float and strainer, are above the water, thus being immune from corrosion or becoming clogged up by deposits of slime, dirt or sediment.

A foot valve inside the strainer seals the suction pipe the moment the drainer stops working, holding the water in all pipes, so that it is always primed ready to start instantly at the next filling of the sump. This foot-valve construction also prevents flooding by back flow.

It takes up not over one-third of the space of other makes owing to the patented construction of float around the suction pipe.

Made in eight sizes.

Minimum capacity 110 gallons per hour.

Maximum capacity 4,000 gallons per hour.

No slow leaks or dribbling of water, as in some drainers for this reason:—The float arms are slotted. This prevents the valve from opening until the water has raised the float to the highest point, and as the water is ejected the float travels down the length of these slots before its weight shuts off the valve; an excellent feature in this drainer.

There are no leather washers used in its construction, and all parts, except strainer, are made of brass.

The drainer costs less than other drainers not as efficient.

PROTECT YOURSELF FROM THE DAMAGES OF SPRING FLOODS AND RAINS. INSTALL THE PENBERTHY CELLAR DRAINER

Manufactured by

Penberthy Injector Co., Limited **Windsor, Ont.**

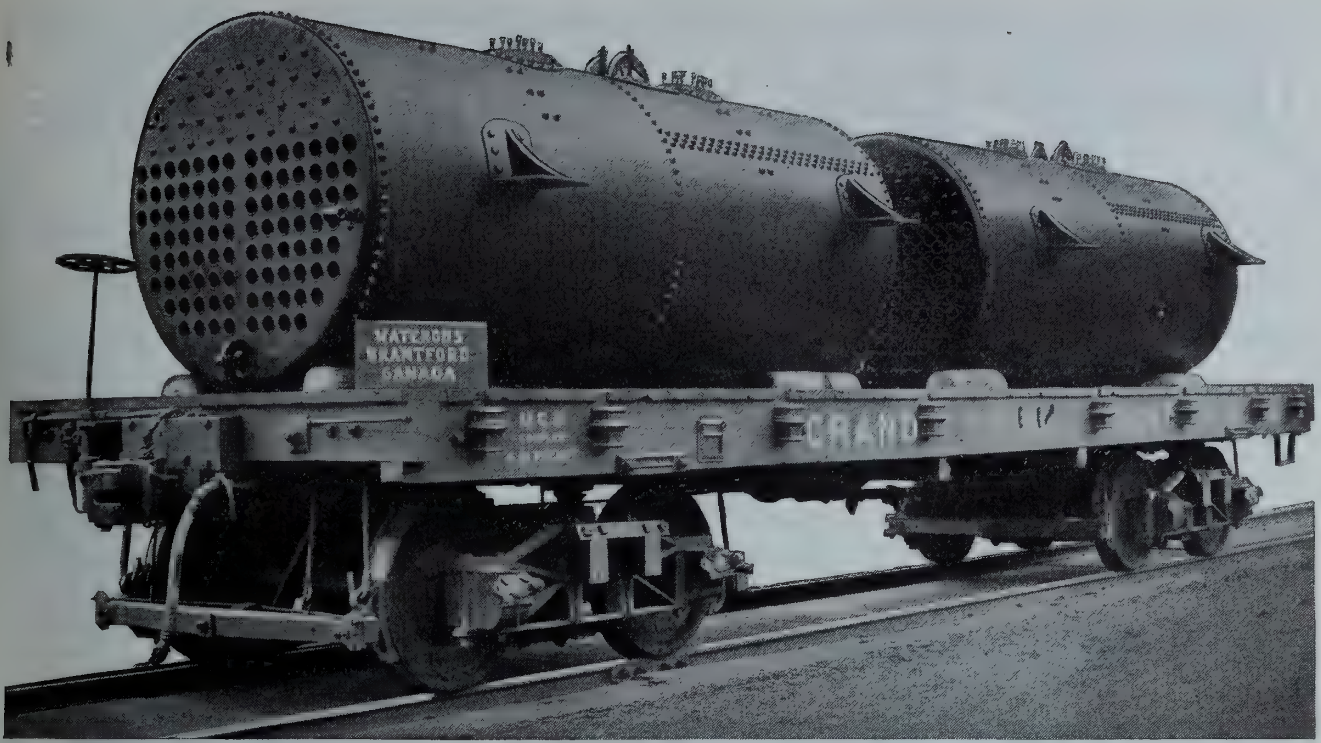
25 Years On The Job

Twenty-Five years is a long time—a quarter of a century—and being the last quarter of a century it means that there have been more and greater changes than in any previous thousand years of mechanical advancement. Machines have changed, telephone, automobile, aeroplane and wireless have been made practical, steam pressures have increased for *some* service but soft packings are still used and will be always for there is nothing that holds flange joints tightly, where there is expansion and contraction like good old *Rainbow* Packing. "*Rainbow*" has not changed in the least in twenty-five years. It is still the good pure Para Rubber secretly compounded packing that has held in some cases for over seventeen years—and good when taken out.

All Rainbow Packing is *red*—all red packing is *not* Rainbow In placing your order insist that your red packing bears this trade-mark and you will get the genuine. ☞ RAINBOW RAINBOW RAINBOW

Manufactured Exclusively by **PEERLESS RUBBER MFG. CO.** **16 WARREN ST. NEW YORK**

FOR SALE EVERYWHERE



Waterous Boilers

Mean Economy In The Power Plant

IT is no trick to get the full steam value from the fuel you burn if you use Waterous Return Tubular Boilers installed the Waterous way.

Combined with the natural advantages possessed in general by this type of Boiler—economy in fuel consumption, large steaming capacity, ability to use hard and dirty water, and comparative low cost—we can furnish you with a boiler setting that is designed and dimensioned to best handle the fuels you use.

Whether you are burning coal, wood, sawdust or shavings, or combinations of these, we will install your boiler to give you the highest efficiency and the most perfect combustion possible with your particular fuel.

We build and carry in stock Return Tubular Boilers up to 72" x 18'. If we cannot supply you at once from our yards we can turn out your order in quick time. Ask us for prices on the next boiler you buy.

Dunham Vacuum Heating Systems

This heating season will not last much longer, but it has probably been long enough even now for you to discover many things about your system which are unsatisfactory. Your troubles can be eliminated by using a good vacuum system of heating.

So first of all investigate a Dunham Vacuum Heating System. You'll find that it:—

¶ Eliminates air binding in the radiators.
¶ Does away with the use of air valves, which either sputter and spit steam and water over everything or keep the air in the radiator.
¶ Permits circulation through every radiator in your office or plant at a pressure of not more than one pound.
¶ Eliminates all water hammer and consequent annoyance from that source.
¶ It eliminates freeze-ups.
¶ It saves money in repairs and actual fuel consumption.
¶ It prohibits the loss of steam into the return lines.

Get busy early and secure estimate on changing your system over this spring or summer. The saving next winter in time and fuel will pay half the expense.

THE DUNHAM RADIATOR TRAP performs the functions of a Radiator Steam Trap perfectly and continuously. Eliminates water and air without loss of steam. Write us for particulars and Bulletins.

Frost King Babbitt Metal

Is the result of 35 YEARS' EXPERIENCE in metal mixing and we believe it is absolutely perfect.

For high-speed machinery and engine work it is without an equal. It is specially designed for Saw Mills, Planing Mills, Threshing Engines, Traction Engines, Pumps, Rolling Mills, and Pulp Machinery, and all classes of stationary engines.

If your dealer does not stock "FROST KING" write us and we will take pleasure in making you a shipment of a 25-pound box.

OUR MIXED METAL SALES AMOUNT TO $5,000,000 ANNUALLY.

POTATO SCALE

BOILER CLEANSER

Would you feed your boilers on dollar bills? Would you order your firemen to fill up the stoker hoppers with nice, clean "greenbacks" fresh from the bank?

Of course you wouldn't!

You'd know that a dollar will purchase a great deal more calorific value in coal than it will give as feed under a boiler.

You wouldn't do this—you're a sane business man—yet you allow your boilers to accumulate scale that effectually prevents all but a small percentage of the heat you get out of your coal, from reaching the water it's intended for.

And you grouch at the cost, and go on "feeding with dollar bills."

Potato Scale Boiler Cleanser goes right to the root of this scale trouble—the feed water. Fed into your boilers in the manner and quantity we prescribe, it will quickly clean tubes and sheets of all adhering scale. And its continued use will prevent any new scale forming.

Send for a keg now. We guarantee it.

But do it now. Dollar bills aren't so very plentiful.

We sell 4 kinds of BOILER GRAPHITE

REPEAT ORDERS TESTIFY

to the reputation that "**Polson**" **Boilers** have gained for correctness of design, construction and general all-round efficiency; to the number of satisfied users who are content to put their steam-raising problems up to the Polson Iron Works; to the high esteem in which they are held by engineers all over the country.

These two boilers were built to fill a repeat order from the Consumers' Gas Company, Toronto. They are of the return-tubular dry back type, each 11 ft. 6 inches diameter, and 15 ft. long. They are fitted with Morrison Furnaces and Adamson Furnaces with Galloway Tubes.

How about your boiler problems? We can give you the same service.

No Leaky Brick Setting

Did you ever spend hours, perhaps whole days, picking out the old mortar from between bricks, re-pointing, painting porous bricks, and patching up loose door frames?

If so, you would like the

Robb-Brady Scotch Boiler

It has no brickwork. There can be no infiltration of air to dilute and cool the gases.

It is internally fired; the gases are completely surrounded by water-heating surfaces from the time they leave the grates until they reach the uptake. But it is different from other internally-fired boilers—the water doesn't stand still, it circulates rapidly and positively, sweeping the heating surfaces clean, insuring rapid and economical steaming.

There's no flat-top combustion chamber to worry about or clean, no girder stays or crown bars. Short-screwed stay bolts only are used and the tube sheet and back inside head are not called on to support crown bars.

How the Robb-Brady boiler secures rapid circulation without a pump or other external device is explained in Bulletin No. 7. Send for it.

Perolin

Harmless to Metal

GUARANTEE

We guarantee PEROLIN, the German Boiler Metal Treatment.

1. To loosen scale already formed in the boilers by its mechanical action;

2. To Prevent New scale from forming;

3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;

4. To correct troubles caused by oil and grease getting into the boiler water;

5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;

6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;

7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;

8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

File No C-5827-1 - G-21287 - HEW

The Perolin Company of America,
1112-1132 W. Thirty-seventh St.,
Chicago, Illinois.

Gentlemen:

Below we give you our report of tests made on a sample marked "Perolin German Boiler Metal Treatment" received from you February 12th, 1913.

The object of our laboratory and practical tests was to determine the efficiency of this compound in preventing and removing boiler scale -- also its action, its effect on boiler tubes and liability to be carried over from the boiler with the steam.

Analysis shows that this product possesses considerable merit in preventing the formation of scale in a boiler. Apparently it does not have any chemical action on the scale, but it appears to break and favors the mechanical removal of the scale.

The product is a good transmitter of heat, and is non-corrosive to the boiler plates.

It is non-volatile and the distillation test showed no volatilization nor entrainment of the constituents with the steam.

We enclose here-with complete data of the methods employed and the results in determining the above conclusions.

Respectfully submitted,

HEW/R

Robert W. Hunt & Co

Why not draw this to the attention of your employer? It is not a boiler compound—it's a **German Metal Treatment** that **loosens** old scale so that it can be readily removed. It forms a preservative film over the tubes when old scale is removed—this film prevents scale-forming substances from adhering, is a good transmitter of heat and prevents pitting, corrosion, etc.

"Perolin" will save you much time and labor, and your employer much fuel and trouble.

Call his attention to it now—get him to order a trial quantity. The results will be pleasing to you both, and you will be in a better position for a **raise in salary**.

"THE Cyclone"

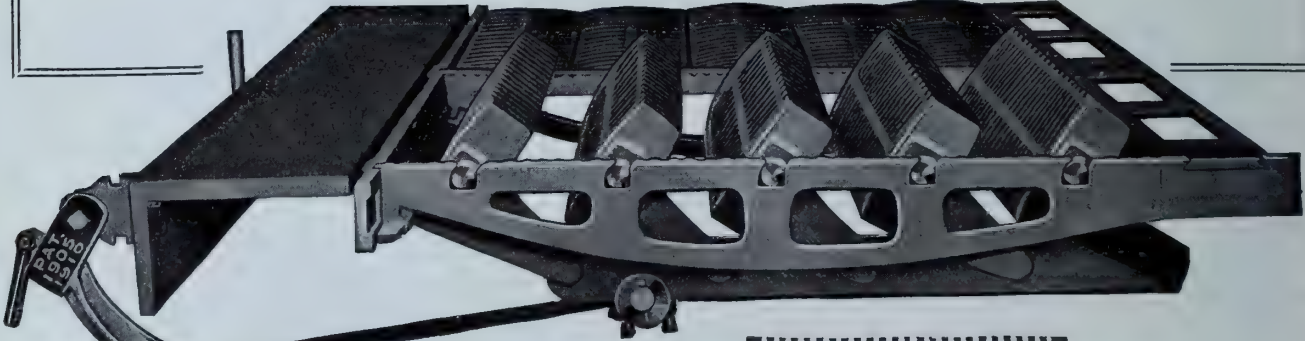
Shaking and Dumping Grate Bar

enables the engineer to fire light and cut off the ash without letting unburned fuel through, with the fire doors closed.

The "Cyclone" allows 68 per cent. of air space and 90 per cent. underdraught.

The combustion is so perfect that the cheapest grades of fuel can be used with equal to that of the best. This means a **big saving of fuel.**

Locks level. Cannot get out of adjustment or become warped. Cyclone Grate Bars are fully guaranteed in every respect—and they live up to our claims everywhere. **Users will tell you too.** May we get you in touch with some of them?



BEWARE OF IMITATIONS.

There are imitators who claim that their gates are as good as the "Cyclone."

If any of them pay you a visit ask them to prove it—they can't.

Stop Blow-outs and Leaks in Pipe Lines by Using GOETZE No. 2 ELASTIC GASKETS

If you start right now to renew with No. 2 ELASTIC GASKETS, you can steadily reduce your renewals until you have brought them almost to the vanishing point.

This is not a mere "claim"—it is backed up by a *guarantee*—in fact the strongest guarantee ever made by a gasket manufacturer.

Think what it means to re-gasket a joint so it will *keep tight for years,* instead of days or weeks. Think of the saving resulting in gasket costs, labor and shut-downs.

What No. 2 Elastic Gaskets Will Do

No. 2 Elastic Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight. Prevent leaks, blow outs and shut-downs. Will practically eliminate renewal expense for gaskets.

No. 2 Elastic Gaskets are for high pressure and super-heated steam lines, but owing to their indestructible nature, are equally adapted to *any and every condition* about a factory, mill or refinery.

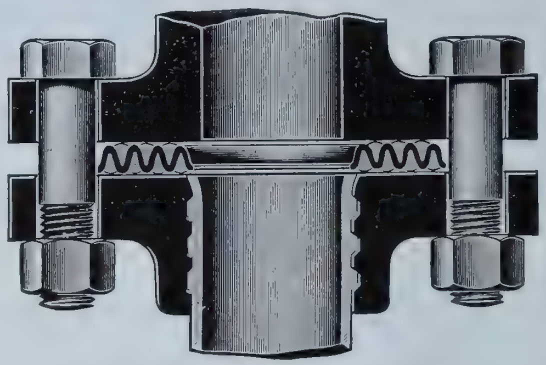
The No. 2 Elastic Guaranteed

Every No. 2 Elastic Gasket is Guaranteed for 5 Years' Continual Service in the Same Joint

There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every No. 2 Gasket whether bought direct from us or through a dealer.

How No. 2 Elastic Gaskets are Made

These Gaskets are made of corrugated copper with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.



Goetze Gaskets are carried in stock by

Name ....

Address ....

....

Theory and practice, science and experience all agree that on the common point that a solid rod packing or a badly-constructed one of any other type cannot prevent friction. There is common agreement also on the fact our self-setting, sliding-wedge packing does save 80 to 90 per cent. of friction.

DANIEL'S ROD PACKING

P. P. P.

COIL RING SPIRAL

What Mechanical Engineers Say

"Tests showed that it required **fifty per cent. more frictional horse-power** to run an engine with high-grade (solid) ring packing than required to run it with P. P. P., and **fifty-nine per cent. more frictional horse-power** to run it with gum-core packing than with P. P. P. Packing, effecting a saving by the use of P. P. P., in the case of the high-grade ring packing of 1.96 horse-power, and a saving over the gum core of 2.31 horse-power."

If you are using solid ring packing or gum core and know the cost per horse-power per annum in your plant, you can easily figure the sum P. P. P. Packing would save in your fuel account each year.

What Operating Engineers Say

"I am using Daniel's P. P. P. Packing with good results. Have tried several kinds but none equals P. P. P."

"I find after using several different kinds of packing on our Corliss engine that P. P. P. is the only one that stands the test."

"I am a stationary engineer and having run all kinds of engines, during my experience packing these engines, I have used most every packing known, and to my satisfaction, I have found P. P. P. Rod Packing the best I have ever used. I also find that P. P. P. cuts out most of the Sunday work, packing engines."

Your dealer ought to carry P.P.P.—if he doesn't, write and we will tell you who does.

BOWSER
ESTABLISHED 1885

Central Oil Clarifying System

The Bowser Gravity Tank

Illustration to the left shows the Bowser overhead gravity tanks fitted with wall indicators and equipped with high and low level electrically operated alarms. The oil is automatically controlled by a pump governor to any level.

These overhead tanks have sufficient capacity to keep the entire Woolworth Building Power Plant supplied with oil for eight hours' time.

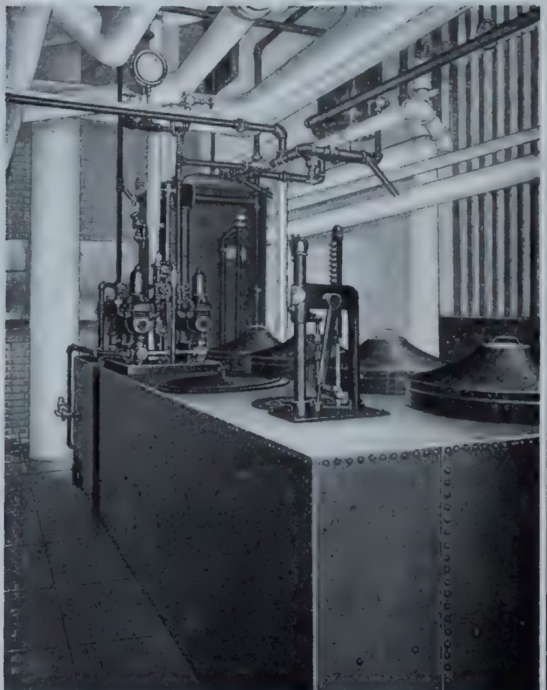
View at the right shows engine room and method of concealed piping. Not a drop of oil is wasted and the friction is cut down to the minimum. Every working part of the machinery is flushed with oil—no part is neglected.

A Bowser system of the proper size will pay for itself in its saving of oil alone in a comparatively very few months' time and its upkeep is negligible.

The Bowser 2F4 Type Oil Clarifying System

The Bowser Oil Clarifying System is placed in the basement of the Woolworth Building below the lowest bearing so that the oil will run to the filter system by gravity. First the oil is heated and separated from the entrained water, which is ejected automatically; then the oil passes over a series of precipitating trays through the filter section and is stored ready for use.

It is recognized by the highest engineering authorities that the "squirt-can-oil-hole" method is antiquated, wasteful, disastrously insufficient in supplying lubricant and in its insufficiency causes many shut-downs and delays that could be avoided by installing either a Bowser Central Oil Filtering and Clarifying System or a Bowser Individual Oil Clarifying Unit.



As installed in the Woolworth Building New York

A Bowser Oil Filtering and Circulating System is the logical oil clarifying device for the engineer, because it is complete and comprehensive in construction and *simple* in operation. It is built upon the "Dry System" and is Bowser-made throughout—

Bowser-made Filter,
Bowser-made Fittings.
Bowser-made Pump.
Bowser-made Castings, in fact everything is made in the Bowser factory. That is one reason why the Bowser blanket guarantee assures you that every part will work properly.

The Bowser Line

We manufacture *Central* or *Individual Oil Clarifying Devices* with capacities from 5 to 7000 gallons or more of filtered oil per day.

We will install a complete Central Oil Clarifying System and turn it over to you in service or we will furnish you an Individual Outfit, or the filter only, or each system complete with instructions how to erect it.

Remember the name "Bowser" has been before the public for over 29 years and has over a million users and boosters behind it.

An inquiry will not obligate you in the least, and may assist in solving that oiling problem.

When the Boss Needs a New Chief Engineer

will you be able to take the job?

Can you operate every machine and all the apparatus in the plant?

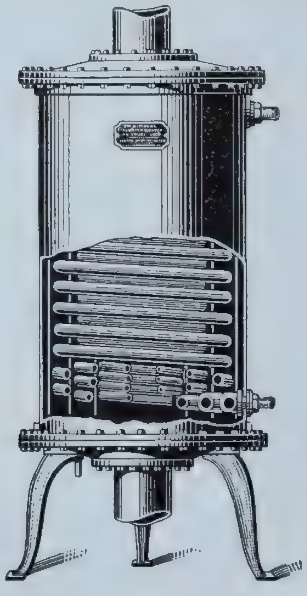
Can you figure the coal saved by heating the feed water with exhaust steam?

Can you tell whether to use a closed or an open heater?

Do you know how big the heater should be?

Do you know how to pipe up both primary and secondary heaters in a condensing plant?

Be perfectly honest with yourself. If you don't know all about feed water heaters, send for the new catalog No. 51 describing



NATIONAL

FEED WATER HEATERS

Hot feed water—if it can be had at no expense—is recognized everywhere as the way to reduce fuel bills and reduce the wear and tear on boilers by eliminating those violent strains caused by feeding a hot boiler with cold water.

The National Pipe Bending Co.

91 Lloyd Street, New Haven, Conn.

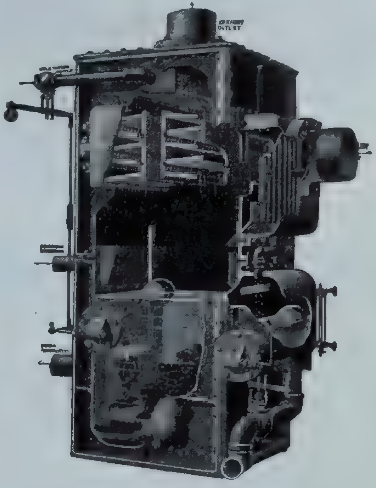
46-62

Is Your Closed Heater About Worn Out, Leaking Badly, Or Filled With Scale? What Temperature Do You Get?

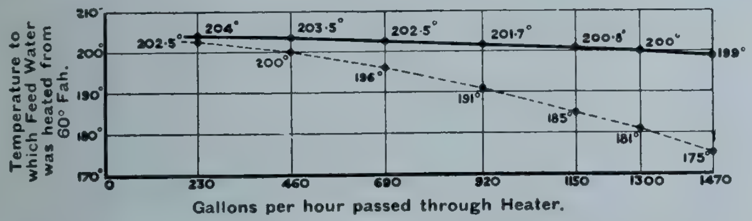
At best a closed heater rarely gives better than 180 or 190°F., when supplied with a surplus of steam at 212°F., besides it wastes the condensates. Then it is only a heater, that is, it does not purify the exhaust steam, does not purify the water or drive off corrosive gases dissolved therein, does not serve as an automatic raw water regulator, and cannot be used as a return tank or hot well, all of which functions, however, are performed by a

COCHRANE OPEN FEED WATER HEATER

Showing how scale accumulates in a closed or pressure heater and the evident difficulty of removing it.



Interior View of Cochrane Open Feed Water Heater and Receiver.



The above diagram shows graphically the results of Tests carried out with a new 1,300-gallon Closed Heater using exhaust Steam at atmospheric pressure.

At the rated capacity of the heater the temperature of the outflowing water was 200°, as shown by the full line, but in this case the water heated was only twice the weight of the exhaust used, so three times the theoretical amount of exhaust was required.

The dotted line shows a test with water 6.4 times the weight of exhaust used—near the theoretical amount. Note the temperature of 181°. A Cochrane would give 210°.

Therefore before ordering a new closed heater, or new tubes or other repair parts for your old one, look up the cost of the latest improved model of the Cochrane Open Feed Water Heater. The interest and depreciation on the difference in cost will be offset by the value of the 10 or 20°F. higher temperature of the feed water that the Cochrane Heater will give over the closed heater, remembering that each 10°F. represents 1% of fuel.

If you have a large quantity of exhaust steam to be purified of oil, before passing to the heating or drying system and if you need a receiver for the reception of the condensed returns, credit the Cochrane Heater also with the cost of the additional apparatus that would be required to supplement a closed heater, likewise for an automatic make-up water regulator, a steam trap to drain the separator, a feed-water skimmer, and the extra space and piping that would be required to connect the independent appliances.

Educational Talks on Leather Belting.

What Constitutes Good Leather Belting

First—**LEATHER,** possessing in the highest degree possible the following characteristics:

Good driving surface, to enable the belt to operate under minimum tension.

Firmness, that the belt may remain straight, run true on the pulleys.

Pliability, that it may hug the pulley closely, securing a large arc of contact.

Little Stretch, that it will seldom need to be shortened. **Elasticity,** that it may easily take up and let go its load as it travels round the pulley.

Good tensile strength, that it may carry its load without breaking.

Resistance to external condition, such as heat, mosture, chemicals, etc., that it may do its work in any place, at any time, enduringly.

Second—**CEMENT** of the highest quality.

The **cement must be powerful,** elastic and immune to all the destructive forces that leather itself is able to withstand. As a matter of fact, the cement, when properly applied, becomes to all intents and purposes a part of the leather itself.

Third—**WORKMANSHIP and INSPECTION**

Careful and skillful workmanship should go into every process of construction. **Rigid inspection** of each operation is absolutely essential.

In short, high-grade leather belting can be obtained only from leather properly tanned, curried and finished; and that leather properly cemented with a suitable cement, all involving careful construction and rigid inspection of every process.

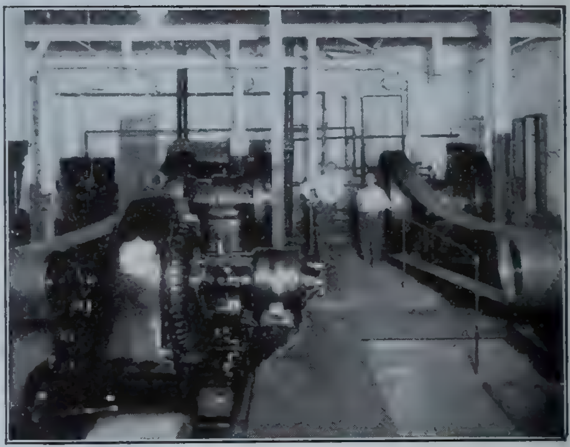
Elmira Machinery & Transmission Co., Ltd.
ELMIRA, CANADA



Two belts in the plant of the Vincennes (Indiana) Electric Co., that have been treated with Cling-Surface for over a year. 14 in. belts; 3 ply leather; 125 h.p. engines; 270 r.p.m.; 115 kw. alternators. Belts run 14 in. slack.

Why Cling-Surface-Treated Belts Pull Best

Taken verbatim from Robert Thurston Kent's article "The Pulling Power of Slack Belts," from Industrial Engineering, May 1913 issue.

"The value of the treated belt apparently lies in the fact that the tension on the slack side of the belt so treated may, owing to the greater coefficient of friction, be decreased to a much lower value than for the belt not so treated, before slip occurs. This decrease in the value is accompanied by an increase in the length of the belt, thereby giving it a greater wrap or arc of contact on the pulley. These two factors both tend to increase the pulling power of the treated belt over that of the untreated belt in an increasing ratio."

Cling-Surface and the direct and indirect economy improvements are now receiving more serious attention than ever from prominent scientists.

The photograph of Cling-Surface-treated belts shown is but one of hundreds with accompanying data which we have to prove the lasting benefits.

Cling-Surface stops slipping, waterproofs, reduces friction, and permits belts and ropes to run easy or slack. Your belt or rope troubles would disappear from the first trial.

Tell us about your belts and ask for literature.

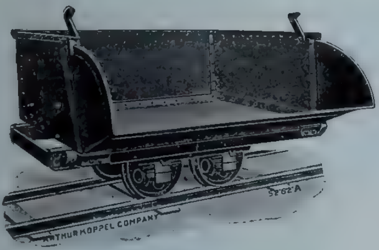
Union Trust Building, - - Winnipeg, Man.



A VERY satisfactory type of car for use in hauling ashes, dirt, etc., is the Scoop Car, which can be dumped either between the rails or to either side. Standard capacities are 12, 18 or 27 cubic feet for gauges of 18 or 24 inches.

How to Charge Furnaces Economically

A very important factor in the problem of keeping a constant supply of power is that of how to stoke furnaces efficiently. We are selling agents for a system of conveying coal and for charging furnaces in boiler rooms which requires very little labor and is practically indestructible. This system consists of the well known Koppel Cast Plate Track and Charging Cars.

ORENSTEIN-ARTHUR KOPPEL

Coal Charging Cars for the conveying of coal to boiler rooms are made of steel and are very durable. They are light in weight and easy and convenient to operate, being designed with special reference to boiler room service. The height of the cars is such as to make shoveling very convenient for the stoker. They may be supplied either with two side doors or end doors, as desired, and with or without swiveling base.

The rails of the track used in our boiler room systems are cast integrally with solid sectional plates, which provide a level surface to walk upon while car is being propelled.

We have a very interesting catalogue on this subject, showing many installations of the Koppel System, together with illustrations of cars, track, switches, turntables, etc., which we should like to send you. Ask for catalogue 412.

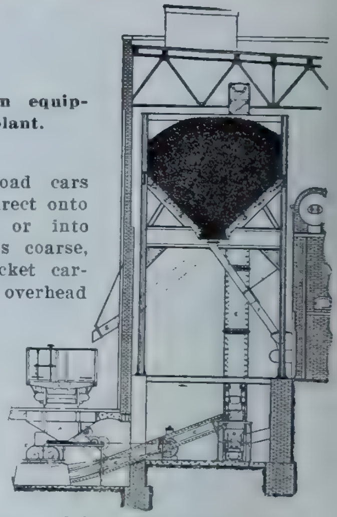
CLEAR

A Jeffrey System makes the handling of coal and ashes an easy problem to solve.

Look at this drawing of an equipment we installed at one plant.

Coal is dumped from railroad cars into hopper, and fed either direct onto an endless apron conveyer or into the crusher when the coal is coarse, and delivered to Pivoted Bucket carrier which elevates it to the overhead bunkers.

Ashes handled from under stokers to Ash Bin by the same conveyer.



We offer you free engineering advice, based upon forty years of experience in the manufacture of Elevating and Conveying Machinery.

Write for our new Bulletin No. 32B.

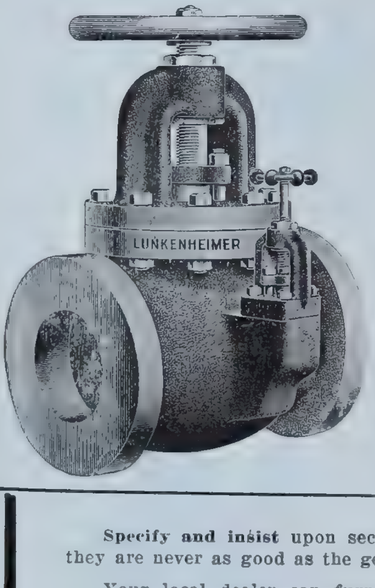
Winnipeg, 601 Union Bank Building



A MOST COMPLETE LINE

of high-grade Iron Body Valves, consisting of Globe, Angle and Cross; Horizontal, Angle and Swing Check; Gate, Blow-off, Pop Safety and Relief; Non-return Safety Boiler Stop, etc. Made in standard sizes and in a number of weights, the heaviest being for steam-working pressures up to 250 pounds per square inch.

LUNKENHEIMER IRON BODY VALVES

are exceptionally durable and strong. The iron used was furnished in the Lunkenheimer laboratories, and has a tensile strength of 25,000 pounds per square inch.

All parts subjected to wear are renewable and are made of a high-grade bronze composition, such as will safely withstand long and severe usage.

For hard service and superheated steam these valves can be had made of **"Puddled" Semi-Steel,** having a tensile strength of 35,000 pounds per square inch, or for extreme conditions of service, pressure and superheat they are made of **Cast Steel,** the tensile strength of which is about 80,000 pounds per square inch.

Specify and insist upon securing genuine **Lunkenheimer make.** Do not accept substitutes—they are never as good as the genuine.

Your local dealer can furnish them; if not, write us.

A thorough description, with illustrations, is given in Lunkenheimer Catalogue No. 50. If you haven't a copy, write for one now.

PIPE-THREADING

"100,000 nipples cut without one crooked thread"

THIS big, clean job turned out by a Chicago concern could be done only by an accurate, fast, ever-ready tool—they found it in the No. 300A model of Oster pipe-threading tools. The capacity of this machine for miscellaneous threading is unlimited. It will thread nipples—short bends—bolts—as readily as regular work. Interesting and complete information is contained in our "List 28." **Clip the coupon.**

OSTER TOOLS

The newest big-seller is the littlest OSTER

THIS die-stock, containing a surprising number of big features for so small a tool, has greatly simplified pipe-threading jobs of ¼-in., ⅜-in., ½-in. and ¾-in. Bulldog Die-Stock No. 81 is a fast-working, self-contained stock. No extra dies to carry, no loose parts to lose—important points when it comes to time-saving and convenience. Big, interesting features of No. 81 are described in the new pamphlet which we have had to publish on this new tool. **Clip the coupon.**

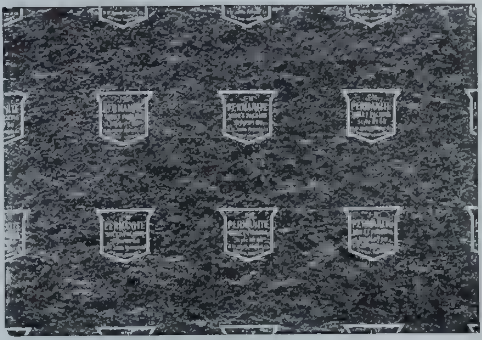
J-M Permanite Sheet Packing

Must Make Good or We'll Stand the Cost



We want you, Mr. Engineer, to give J-M Permanite Sheet Packing a trial. We want you to test it on the most troublesome joints in your plant—joints that require your constant attention with other packings.

Our faith in what J-M Permanite will do for you prompts us to accept your order and let you try it entirely at our risk.

You can be the judge, and if J-M Permanite doesn't make good—if it fails to end the troubles these joints have been giving—if it fails to make them permanently leak-proof, then return what you have left and we'll refund the full amount of our bill. The trial won't cost you a cent.

Surely it's well worth your while to find out under the protection of our money-back offer, whether J-M Permanite Packing will put an end to those leaky joints and all the vexations and delays they cause.

Send your order to our nearest branch to-day with the above understanding, stating the conditions you have to overcome and size of packing desired.

You can't lose on this straightforward offer, for we take all the risk.

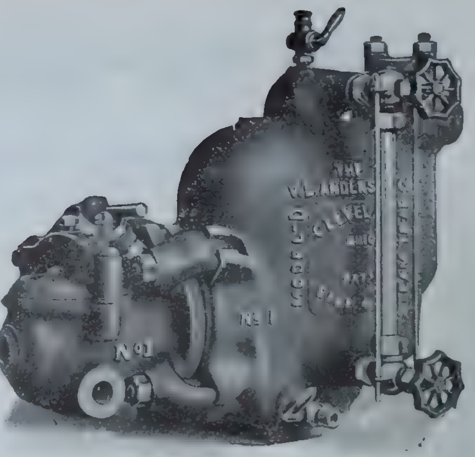
NATIONAL TRUST BUILDING - TORONTO



Condensation is its "Open Sesame"

In the story of "Ali Baba," in the "Arabian Nights," we are told how the ponderously massive doors, that guarded the robbers' cave, while remaining unassailable to attack and impervious to the most skilled locksmiths, would swing open of themselves, at the mere repetition of the magic words "open sesame."

And like them, the

Anderson Model "D" Steam Trap

guarding the exit from your steam lines, remains immovable before the onslaught of the highest-pressure steam, yet opens instantly and is a ready means of egress for the condensation just as soon as it arrives.

To steam, the Anderson is a door, locked, bolted and barred—to condensation it is an open road, clear "as the hole through the pipe."

Ruggedly built, for the hardest service, it will stand up and perform its duties, year in, year out. Its quickly-changed valve and seat suit it for all pressures; its water gauge allows you to keep a tag on how it behaves; its interchangeable construction makes replacements easy.

Get the booklet of the Anderson. It gives in detail, its many special features.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

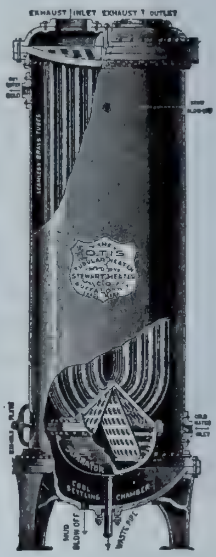
There Are Over 800 Otis Heaters in Buffalo Alone



Throughout the various states, thousands upon thousands of horse-power are in use.

Why this popularity?

Because Otis Heaters occupy a place in the engineering world that is second to none.

It is the only pressure heater made that contains an effective oil separator and cool settling chamber.

The exhaust is the heating agent, and 212° is the ordinary, not the spasmodic, temperature of the water.

The Otis has unusually large capacity and heating surface, and is tested under 200 lbs. hydrostatic pressure.

There's a "rock-ribbed" guarantee that covers every function and part of the Otis Heater.

Try it for 30 days at our expense. You have nothing to lose, and much to gain.

Catalog on request.

His Faith Was Well Founded

2256 E. 85th St., Cleveland, O., May 11, 1912.

Gentlemen:—Two years ago I had occasion to babbitt several bearings upon machines which ran upon reverse motion, carrying a heavy load. It is now two years since it was done, and at last accounts bearings still in A1 condition. When I insisted upon wanting MAGNOLIA METAL, was asked why I was so particular. I simply said time will tell. I had used it before and say to any Engineer who may have a troublesome bearing—"try MAGNOLIA METAL, and your troubles cease." To prove its worth I bought it myself, and found the proof was in the using.

Yours truly,

GEO. STANFIELD, Secy.,
No. 5, N.A.S.E.

A. J. WORTMAN
Steam, Gas, Hydraulic and Pneumatic Engineering

Bellaire, O., Dec. 20th, 1910.

Gentlemen:—My experience with MAGNOLIA METAL, though brief, becomes interesting in demonstrating the peculiar fitness of this particular kind of metal.

The crank pin on one of a pair of twin engines driving a two-stage centrifugal pump persisted in running hot, and we tried plain brass and two kinds of babbitt without success. A liner of MAGNOLIA METAL was run in—that was about three years ago, and it is still running about 15 hours per day, giving no trouble whatever. It ran cool right from the start.

Yours very truly,

A. J. WORTMAN, Chief Engineer,
Benwood Water Co.,

THE TRANSFORMATION

¶ In the transformation of energy, do you stop to realize where your energy comes from?—Where the base of your power really is?—Where the big cost is?

THE COAL PILE

¶ Use every means to prevent waste in your power plant, but—

GET THAT COAL PILE RIGHT

Apply scientific methods of buying:

FIRST:—Select the proper coal.

SECOND:—Specify what you require.

THIRD:—Get what you pay for—or—pay for what you get.

YOU MAY burn your coal efficiently; evaporate your water efficiently; convert your steam efficiently—BUT

REMEMBER THE COAL PILE

¶ Your economic methods for increasing efficiency should start at the real beginning of the expense.

Let us point the way to increased efficiencies all along the line! Our service includes:—

(1) Coal testing.
(2) Furnace and Boiler testing.
(3) Treatment of water supply.

THIS IS THE SERVICE YOU NEED

THE TORONTO TESTING LABORATORY,
LIMITED

160 Bay Street -:- Toronto

ENGINEERING CHEMISTS

IMPORTANT:—

We advise the proper treatment for your feed water, according to the analysis of your water supply.

THE SCIENTIFIC WAY.

We do not sell Boiler Compounds.

GET
OUR
SERVICE
INTO
YOUR
SYSTEM

IMPORTANT:—

We conduct complete Boiler Trials, including furnace testing, coal testing, flue gas analysis, etc. IF YOUR CHIMNEY EMITS SMOKE, CONSULT US.

G. & McC. VERTICAL QUICK REVOLUTION STEAM ENGINES

Will give you as they are giving others wherever installed

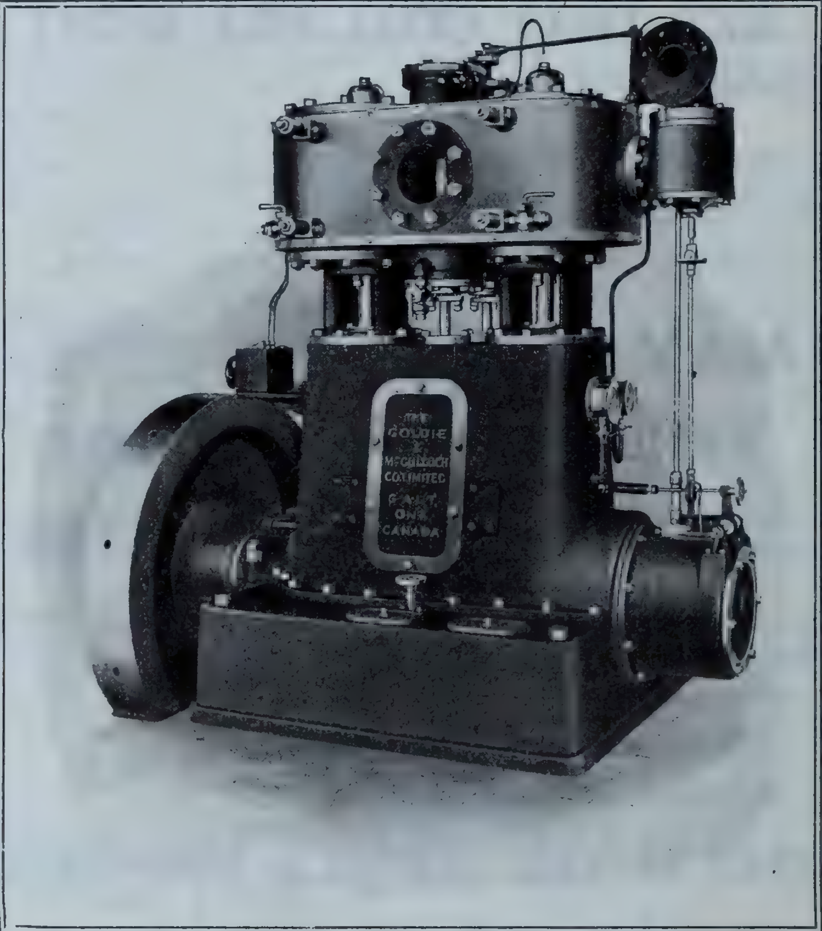
A MAXIMUM OF SERVICE

At a Minimum Cost of Upkeep

These Engines have a Perfect System of forced Lubrication.

They require little or no attention while running.

Built in all types and sizes.



Two Cylinder Compound, Vertical Forced Lubrication, Quick Revolution Steam Engine, with Combined Throttle and Expansion Governor.

They run with Practically no Noise or Vibration.

All working parts are very easy of Access.

Built to suit your Particular Requirements.

All the materials used in the Manufacture of Vertical, Quick Revolution Engines must be the best obtainable. In the construction of our Engines particular attention has been paid to this feature; the materials supplied being in accordance with **British Admiralty Specifications.** All Engines are tested under steam before leaving our works.

We shall be pleased to furnish Specifications and further information.

Power, Light, Heat Features at Central Y.M.C.A., Toronto

Staff Article

Like public institutions generally, the Young Men's Christian Association of Toronto, have endeavored as far as possible to place their new building in the all-comprehensive unit class, and in none of the many excellent features to be noted in the general layout, equipment and furnishing is this more apparent than in that of the particular section to which this article pertains.

APPROPRIATE ceremonies marked the opening of the new central building for the Y.M.C.A., Toronto, on October 26th, 1913. The new building, together with the various branches throughout the city, provides exceptional facilities for the carrying on of the work which is associated with that institution. It has a frontage of 186 ft. on College street, a depth of 202 ft., and is of brick construction, four storeys high, with basement and sub-basement, while in the centre is a light court 70 by 50 ft. The architects, Burke, Horwood & White, Toronto, have designed a building on modern lines, and, at the same time, typical of this class of institution. The equipment generally is in accordance with the latest ideas.

COLLEGE STREET FACE, CENTRAL Y M.C.A., TORONTO.

On the third and fourth floors are the bedrooms and an emergency hospital. The classrooms and auditorium are on the second floor, while the offices, reading rooms, main and auxiliary gymnasiums are on the main floor. In the basement are located the bowling alley, billiard room, lockers, and cafeteria. One part of the sub-basement houses the swimming pool, while the power plant and general auxiliary equipment is in the other. The latter, again, is subdivided for boilers, engines and generators, filters, pumps, and ventilating plant respectively. The power plant is a complete unit, and represents a good example of an independent installation. The equipment is of the highest class, and of sufficient capacity to more than take care of present requirements, while the layout is such as to enable the best results to be obtained.

Boiler Room.

The boiler room equipment consists of four horizontal return tubular boilers, each of 125 h.p., 66-inch diameter by 16 ft. long, and of a working pressure of 100 pounds. The boilers were supplied by the John Inglis Co., Toronto, and are equipped with "cyclone" shaking grates and auxiliary injectors. The damper in the uptake breeching is fitted with a "Spencer" damper regulator, which is controlled by a "Johnson" thermostat. The coal bins are under the sidewalk and in front of the boilers. A "Turnbull" freight elevator is installed for the lifting of ashes, etc., to the street level. The elevator is operated by hydraulic pressure from the city mains, and has a capacity of 2,000 pounds.

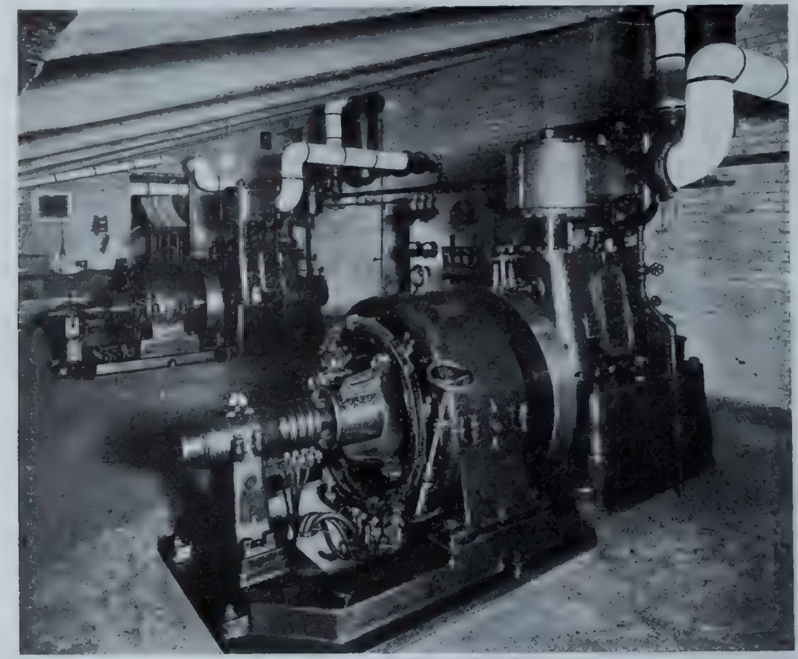
The boilers are blown off into a tank which drains into a sump, in which operates a "Deming" centrifugal pump having a capacity of 300 gallons per minute. This pump is direct-connected to a 2-h.p. "Swaby" motor. All the high pressure piping is extra heavy pattern, and includes "Crane" extra heavy fittings. The steam header is 9-inch diameter, with 5-inch diameter leads from each boiler. The exhaust pipe from the main engines to the heating system or atmosphere is 8-inch diameter. All the high pressure piping is covered with 85 per cent. magnesia, and the low pressure with asbestos "air cell" casings 1 inch thick.

BATTERY OF RETURN TUBULAR BOILERS.

Engines and Generators.

The generating equipment consists of

two high-speed, vertical, enclosed, engines, each direct connected to a Bruce-Peebles direct current generator, one set being 75 k.w. and the other 60 k.w., both running at 550 r.p.m. The generators are three-wire, 230/115 volts, and were installed by R. H. Nichols, Toronto.



ENGINES AND GENERATORS, CENTRAL Y.M.C.A.

The engines have each two cylinders of 10 in. diameter by 6 in. stroke, and were supplied and erected by the Goldie & McCulloch Co., Galt, Ont. The switchboard was supplied by R. H. Nichols, and has three grey marble panels—two generator and one distribution panel, each equipped with the usual recording instruments and switches. At the back of the switchboard are four balancing transformers. Cables are laid from the main switchboard to a distributing board located in an adjoining room. This board is of polished black slate, and was supplied by the Canadian Krantey Electric Manufacturing Co., Toronto. Current is distributed from this board to all the motor-driven equipment and also to the distributing panels, for lighting, on each floor.

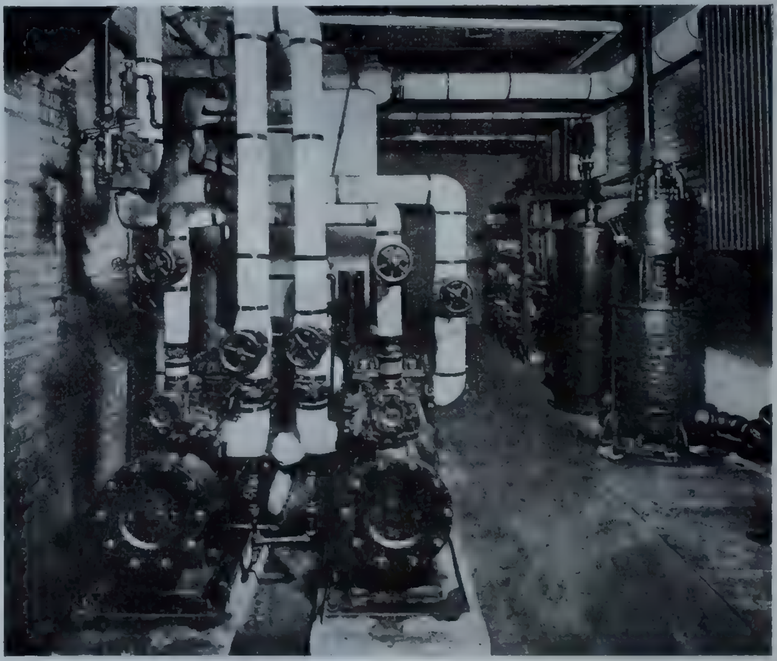
Pumps and Heater.

In the pump room adjoining the boiler-room are installed the boiler feed and vacuum pumps, "Webster" feed water heater, vacuum cleaner, and the distributing switchboard already referred to. A "Burnham" 9-14-12 vacuum pump delivers the returns from the heating system, etc., to an overhead receiver, from which they flow into the 500 h.p. open-type heater. The boiler feed is taken care of by two "Burnham" 10 7-12 pumps. These pumps and heaters were supplied by Darling Bros., Montreal, and the valves in the piping system by Jenkins Bros., Ltd., Montreal.

Heating and Ventilating.

The building is heated from the main floor up by means of radiators on the "Webster" system, and using exhaust steam from the engine. The steam line to the heating system is fitted with a "Darling" reducing valve which allows live steam to enter the line at a reduced pressure, in the event of the supply of exhaust steam being insufficient. In addition to the above, there is an indirect heating and ventilating system operating throughout the building. The fan and heaters are installed in the sub-basement, and have a capacity of 20,000 ft. of air per minute, the "Sheldon" fan being driven by a 7 h.p. C. G. E. motor. There are two sets of "vent" heaters, between which are fitted a screen for filtering the air. The heaters are automatically controlled by two "Johnson" duct thermostats, which are set at any desired temperature, and automatically close the diaphragm valves on the heaters when the temperature of the air rises one degree above the point at which the thermostats have been set. A directly opposite condition reopens the valves when the temperature falls one degree. The diaphragm valves regulate the steam passing to the heaters, and the thermostats control the valves by means of compressed air. The temperature control system was supplied by the Johnson Temperature Regulating Co. of Canada, with headquarters in Toronto. Compressed air is furnished by a motor-driven compressor.

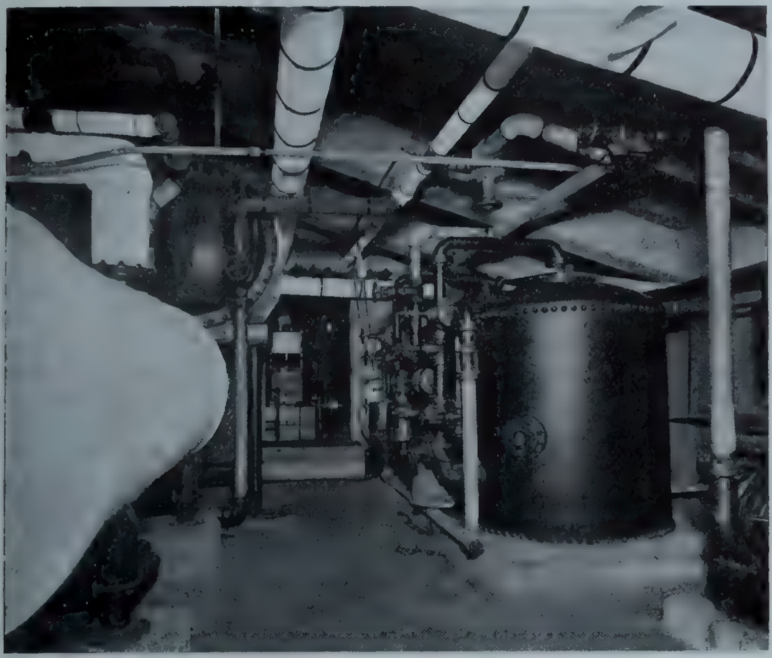
There are four "Sheldon" fans on the roof for drawing air out of the building, each fan operating its own section. The capacities are as follows:—One of 6,100 ft.; two of 7,300 ft.; and one 3,200 ft., and each fan is driven by a "Sprague" slow-speed motor equipped with regulating rheostats. In the air duct to the swimming pool is an auxiliary heater of 150 ft. capacity, which is additional to the main heating system.



PUMP ROOM, CENTRAL Y M C.A.

Filtration Plant.

The swimming pool is 75 ft. x 25 ft., and is 8 ft. 8 in. at the deepest end. The capacity is 80,000 gallons. The water is filtered daily, and for this purpose a filtration plant has been installed in the sub-basement adjoining the pool. It may here be remarked that it was considered better, both from an economical and hygienic standpoint, to clean the water daily rather than use city water direct, and only change the water as is the usual custom, about once a week. The filtration plant consists of two pressure mechanical filters, each having a capacity of 4,000 gallons per hour. The piping is so arranged that the filtered water can go direct to the pool or through the heater to the pool, or that city water may go direct to the pool. The filters are cleaned daily, by reversing the direction of the flow, previously cutting off connection with the pool, and allowing the city water to flow through the filters and out to a sewer connection.

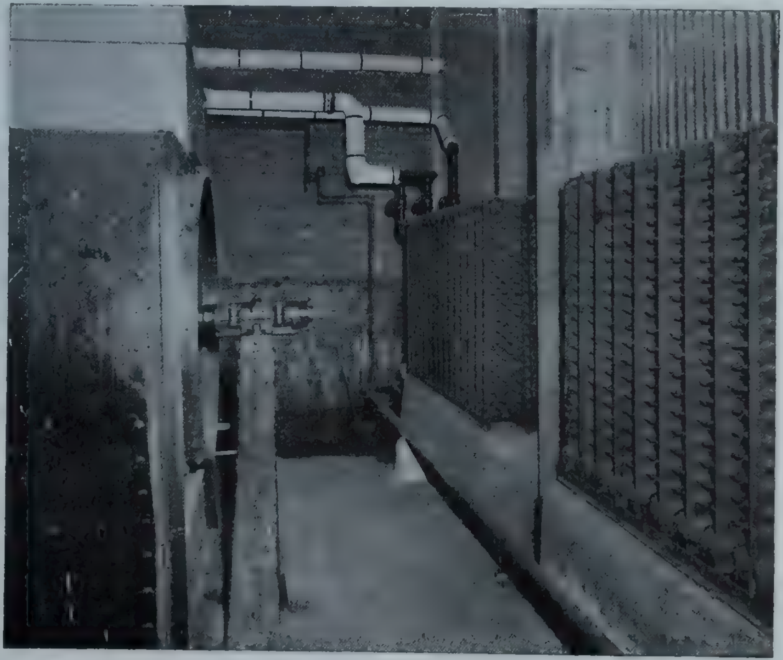


FILTER ROOM, CENTRAL Y.M.C.A.

When the water requires heating, it is passed through a "Sims" exhaust steam heater. This latter has a capacity of 9,000 gallons per hour, and heats the water to 80 degrees or about 75 degrees in the pool. It is fitted with a "Johnson" hydraulic thermostat control system which regulates the temperature of water delivered to the pool, so that it can be varied or maintained to suit requirements. In this case, the diaphragm valves are operated by city water at reduced pressure and under control of the thermostat. The drains from the heater are carried to the hot-well in the pump room. The water is pumped from the pool to the filter by a "Deming" centrifugal pump direct connected to a Bruce Peebles 5 h.p. motor. A Venturi water meter is installed in the pipe line between the pool and the filters, on the suction side of the pump. The pool is faced with white glazed tiles. There are 24 showers for adult members and 14 on the boys' side. The showers have marble trimmings and tile floors. Metallic lockers were furnished by the Hess Heating and Ventilating Co., Chicago.

Lighting.

The main floor and auditorium are illuminated by semi-indirect fixtures, each having three 60 watt tungsten lamps. In the classrooms and offices are semi-indirect fixtures each having one 60 watt lamp. The bedrooms are equipped with 25 watt lamps, and the corridors have 40 watt tungsten lamps fixed close to the ceiling and controlled from the main floor. The gymnasium is equipped with 150 watt lamps, three to each fixture, and under the gallery are 40 watt lamps in single units. The bowling alleys are illuminated by 100 watt lamps in groups of six, and the billiard tables have 40 watt lamps, three to each fixture.



SUPPLY FAN ROOM, CENTRAL Y.M.C.A.

Water Services.

The cold water service is supplied from three tanks situated on the roof and connected to the city mains. The hot water service for the showers, lavatories, and kitchens, etc., is supplied from a "Sims" instantaneous heater located in the sub-basement. The heater has a capacity of 10,000 gallons per hour, and was supplied by H. L. Peiler & Co., Montreal. It is heated by exhaust steam and is fed from the city mains. Above the heater is a storage tank which is equipped with a "Johnson" temperature control system, consisting of an hydraulic thermostat which automatically closes the diaphragm valves in the steam line to the heater when the water has reached a pre-determined temperature. Similarly it opens the valve when necessary. The valve is operated by city water at a reduced pressure, and is under control of the thermostat. The condensed steam in the heater is returned to the feed water heater by the vacuum system. The steam table in the cafeteria kitchen is supplied with steam at 40 pounds pressure, and the return pipe is fitted with "Dunham" trap, as is also the return pipe from the drying room heater.

General Features.

In the pump room is installed a "Spencer" motor driven, vertical turbine vacuum cleaning machine capable of handling four sweepers operating at one time. The machine is connected to piping installed throughout the building, which has sweeper connections on each corridor and in the large rooms. The vacuum cleaner was supplied and installed by Bennet & Wright, Ltd.

On each floor is a "Recti" gong and brake box in connection with the fire alarm system. There are also five standpipes at various points, with connections on each floor. These are equipped with 1½ inch linen hose.

An electric elevator has been installed by the Turnbull Elevator Co., Toronto. It is driven by a 25-h.p. 220-volt motor, and operates from the basement to the top floor.

The layout of the power plant was designed by Williams & Co., consulting engineers, Toronto, who were also responsible for the layout of the general mechanical equipment. Contracts covering plumbing, heating and ventilating, piping and wiring, were carried out by Bennet & Wright, Ltd., Toronto.—Photographs, courtesy of "Construction."

◆

SUBMERGED FIRING.

IN the Zeitschrift fur Dampfkessel und Maschinenbetrieb, recently, Privy Councillor Jaeger gives an account of the Brunler system of submerged firing. He points out that hitherto the construction of steam boilers has been based on the heat produced by the processes of combustion being conducted to the fluid in the boiler through its walls. This system involves very considerable losses both of heat and material. The Brunler "Greek fire" method of submerged firing is at first sight startling, but Mr. Jaeger describes the Brunler boiler which has been used with great success by the Wesenfeld, Dicke & Co., chemical factory at Dahl, near Langerfeld. The boiler plant consists of a cast steel generator in which the flame burns under the surface of the liquid, and of a cast iron collector for the liquid, the steam, and the gaseous products of combustion. The fuel used is coal tar oil.

◆

HYDRAULIC LIFT TROUBLES.

IN hydraulic lifts, states the Vulcan, trouble often arises through water leaking from the ram glands and falling on to the ropes. Where this possibility exists, the ropes should be well protected with a coating of tallow and blacklead well mixed together, otherwise the water will find its way into the interior of the rope, and, by rusting the wires, rapidly weaken them. Several instances of this kind have come to the notice of the Vulcan Company through its inspectors.

The danger in such cases lies in the fact that there is often no external evidence to show that the ropes are unsafe. In one instance the two supporting ropes of a lift broke without warning near to their anchorage to the cylinder, causing the lift car to fall the full height of the lift well, wrecking the lift and killing the attendant. On examination of the broken ropes it was found that the internal wires had been damaged by the water to such an extent that they were quite brittle and without strength, but no broken wires were noticeable before the accident at the point of failure.

The best way to prevent such failures is to design the lift so that water cannot possibly fall on the ropes, or, if this be not feasible, to fit drip trays or other appliances to keep the water off the ropes if leakage should occur.

◆

PRODUCER GAS FROM WOOD.

IN a lecture on "Producer Gas from Wood," recently delivered before the Junior Institution of Engineers, Mr. G. E. Lygo said that gas plant makers had given serious attention to the subject of utilizing wood for use in gas producers. In these plants all kinds of wood, from sawdust to pieces 6-in. diameter, cotton seeds, cocoanut shells, fibre and dust, sugar cane, coffee husks, rice husks, spent tanning bark, rubber leaf waste, surface peat, etc., could, he pointed out, be utilized.

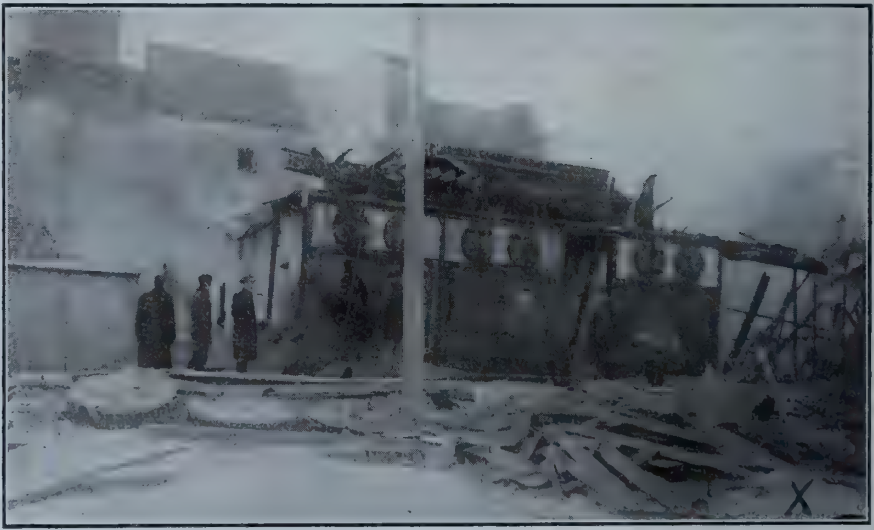
Referring to the design of the plant, the lecturer said many points had to be taken into consideration which were not needed with an anthracite plant. The area of the generator was governed by the nature and size of the fuel, but, roughly speaking, it was 2½ times that required for coal fuel. The depth of the fuel depended upon its size and density. A deep fuel bed was necessary for large pieces of wood, for otherwise air passed through and ignited the gas in the top of the generator

EXPLOSION WRECKS POWER PLANT BOILER HOUSE.

By J. H. Stoliker.

AN escape of natural gas and its subsequent ignition resulted in an explosion which practically destroyed the boiler room of the Chatham, Wallaceburg and Lake Erie Ry. Co. power house, at Chatham, Ont., on Tuesday morning, Feb. 24th. The picture tells a most vivid story of the force of the explosion. The north wall was blown out and the roof was carried clear off its supports. A number of men were in the building at the time, all of whom escaped except Wm. Roberts, assistant chief engineer, John Montague, fireman, and A. S. Davies, engineer in charge. These were all burned about the face and arms. Mr. Davies' injuries proved fatal, as he passed away early the following Friday morning. The leak from which the explosion resulted was caused by the breaking of a stop-cock which controlled the flow of gas through a 1½ inch pipe. The three Babcock & Wilcox boilers were not damaged to any extent and were put in service again the same day.

Mr. Davies had been in the employ of the Chatham Gas Co. for about 10 months, and was considered a careful and efficient engineer. His funeral took place Sunday, March 1, being conducted by the Masonic Order, of which he was a member. The members of the different departments of the Chatham Gas Co. who operated the power house, were present in force, as were also other members of the engineering fraternity. The other two injured men are getting along nicely, and hopes are expressed that they may have a speedy recovery. Mr. Davies was blown out of the building, and was picked up about forty feet away, the spot being indicated by a cross in the picture.



EXPLOSION EFFECTS CHATHAM, WALLACEBURG AND LAKE ERIE RAILWAY POWER HOUSE.

Breakdowns of Stationary Engines, Their Cause and Cure-I.

By Michael Longridge

The accompanying article, which formed the subject of a recent lecture before the Graduates' Association of the Institution of Mechanical Engineers, is one of special interest to power plant operatives. While this is so, the fact that faulty design and careless installation have played a large part in many "smash-ups," the advice relative thereto is such as to be of considerable value to those whose work lies in these particular spheres. The author of the paper is the well-known Chief Engineer of a large and leading English power plant equipment insurance company.

THE subject on which you wish me to discourse is "Breakdowns of Machinery," but that is a far larger field than I can well cover, so I propose to survey one part only—viz., that occupied by stationary steam-engines, such as are commonly used for driving mills and factories, and about these there is much more to be said than I can say in the short space of time allotted me.

Wreck From a Burst Flywheel.

Breakdowns of stationary engines is rather a sensational title for a lecture, and it is possible that some may expect a more exciting story than I am prepared to tell. That such may not be entirely unsatisfied, I will begin by referring to the bursting of the flywheel of a pair of horizontal compound engines, indicating about 400 indicated horsepower, and transmitting that power to a weaving-shed by a spur flywheel hung upon the crank-shaft. Both cylinders had Corliss valves. On the morning of the accident the engine started at 6 a.m. and ran as usual till about 7 a.m., when it began to race. The operatives threw off their looms and ran. The engineer and another man rushed to the engine-room, and with conspicuous bravery made for the stop-valve, which, as usual, was placed between the two cylinders, in a direct line with the flywheel. Before they could close the valve, possibly before they reached it, the flywheel burst and both were killed.

Some of the flying masses cut the traveling crane in two and unroofed the engine-room. Others cut through the wall of the engine-room and ploughed a path to destruction into the weaving-shed, unfortunately injuring four of the weavers who had been unable to escape. The flywheel arms were snapped off short, at their junctions with the boss, and a large piece was torn out of the boss itself, the pinion was broken, and the second-motion shaft—a heavy piece, 8½ inches in diameter—was dragged from its fixings and bent. The engine foundations were dislocated, and the engines themselves moved bodily from their places. Fortunately the cranks and connecting-rods remained connected, and the cylinders were saved, but all the valve-gear was smashed, and the bed-plate of the condensing engine was badly cracked.

Probable Cause of the Disaster.

When the wreckage had been cleared away sufficiently to allow access to the engines, I examined them. I found the governor, the wheels which drove it, and the knock-off gear in order. The front steam-valve of the high-pressure cylinder was open, and the spring in the front end of the dashpot, which should have closed it, was compressed, and cemented coil to coil, and to the walls of the dashpot, by a viscous brown cement consisting apparently of baked grease. The spring remained compressed when taken out. If it stuck fast when the engine was running, the steam-valve at the front end of the cylinder must have remained open, and the racing would be accounted for. In suggesting this as an explanation of the breakdown, however, I should mention that the consolidation of the grease about the dashpot spring may have been due to cold, for, owing to the destruction of the engine-room roof and wall, the engines had been exposed to very cold weather for several days before I saw them. The cause of the breakdown, therefore, is uncertain.

Classification of Breakdown Causes.

In another mishap of a similar nature the wreck was too complete to leave any clue to the cause. Fortunately, smashes so complete are the exception, not the rule. Of 71 breakdowns in 100 the cause can be discovered. The table herewith shows the number of breakdowns attributable to each of four groups of causes, as percentages of the total breakdowns during three consecutive periods of ten years.

Cause of Breakdown.	1881 to 1890. per ct.	1891 to 1900. per ct.	1901 to 1910. per ct.
1. Accidents and causes not ascertained	36	27	29
2. Negligence or ignorance of owner or attendants	19	22	19
3. Structural weakness, bad designing or workmanship	30	30	21
4. Old flaws, defects, or wear and tear	15	21	31
Total	100	100	100

An Improving Statistical Record.

The classification is not very satisfactory, because it is without clear lines of demarkation. It was begun many years ago, and could not afterwards be altered without much labor; but if the figures are not very accurate, their meaning is quite clear. Those in line 1 call for no remark, except that the high percentage in the first decennial period is principally due to want of opportunity for investigation. The constancy of the percentage in line 2 suggests that Board schools have not changed human nature over much; but the reduction in the last column of line 3 awakens hope that the vast sums spent on technical education have not been altogether wasted; and, if we take the figures for each of these ten years separately, hope changes to conviction, for we find the percentage falling more or less regularly from 23 in 1901 to 16 in 1910. If more evidence be wanted, it is given by line 4, which by comparison with lines 2 and 3 reveals how work and age are year by year supplanting ignorance, neglect, bad workmanship, and bad design as causes of breakdowns of steam-engines.

I do not mean to say that improvement in design only began ten years ago, but it was gradual. The substitution of the principles of mechanics and arithmetic for rule-of-thumb was slow, and the replacement of old engines by new was slower still, so that years elapsed before the effects of the change became appreciable; but if progress was slow, it was effective. When I began to collect statistics 34 years ago, engines running for the most part 50 to 60 hours per week broke down, on an average, once in 5½ years; now, though speeds and pressures have been doubled, they break down once in 9½ years. That is what we older men have done. Those who are taking our places are expected to do more; and if it will lighten your task to start it with some knowledge of the casualties from which the several parts of steam-engines most commonly suffer, I am here to tell you all I can in the time allotted to me.

Valves and Valve-Gear Failures.

I begin with valves and valve-gears, because at the present time they fail more frequently than other parts of steam-engines. About one-third of the total number of breakdowns originate in them. The proportion has nearly doubled in the last thirty-five years. It has increased concurrently with the use of Corliss and other complicated automatic trip-gears, made up of many pieces.

Many of those gears are too weak for the abnormal stresses to which all valve-gears are occasionally exposed; but a large proportion of the breakages is due to failures of the screws, bolts, and keys, by which the parts are held together.

Many breakages of valve-gears cause little damage, but some have very serious results. Most "runaways" are due to failure of valve-gears or governor-gears controlling them. Every engine, therefore, ought to have a "knock-off" gear acting on the stop-valve or a special runaway valve. Electric gears which can be operated by pressing a button in any part of the works, as well as by the knock-off motion on the engine, are the best. Valves intended to be closed by springs should be actuated by gears which will close them if the springs should fail, as seems to have happened in the breakdown I first mentioned.

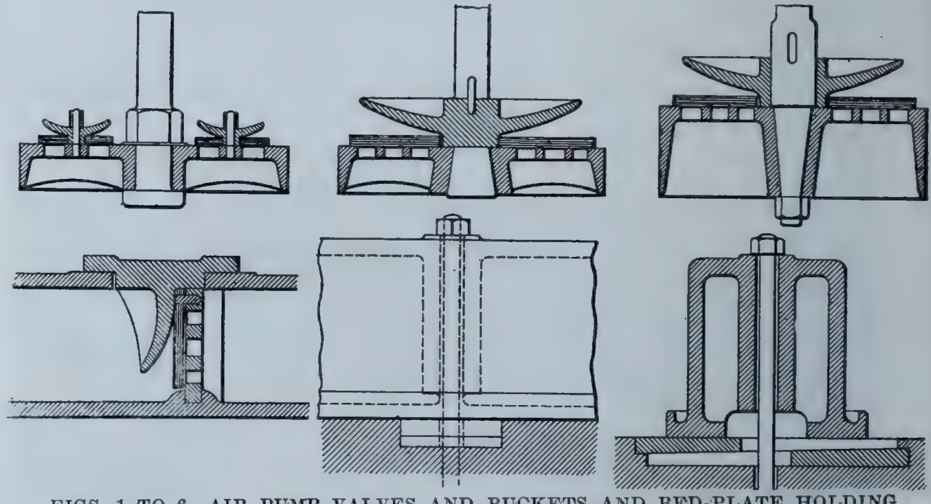
Not a few breakdowns are caused by eccentrics slipping or becoming disconnected from valves, leaving the one or other of the cylinder ports permanently open or closed. When this port is a steam-port of a high-pressure cylinder, a runaway may follow, and when it is an exhaust port, the compression curve may run up high enough to blow off the cylinder end. When the inlet to the low pressure cylinder remains closed, the pressure in the valve-chest or receiver may rise sufficiently to burst one or the other. All these things have happened, and the only preventives I can suggest are large safety-valves ferruled to prevent overloading, not only on the cylinder ends, but also on the receivers or pipes between the cylinders.

Air Pump Motions, Valves and Buckets.

Air pump motions, valves, and buckets are, after valve-gears, the parts which fail most frequently. They accounted for 20 per cent. of the engine breakdowns thirty years ago. They still account for about 16 per cent., and yet some trouble on the part of engine-tenders, and a little thought on the part of engine-builders, would enormously diminish the number of mishaps. The cause of half of them is corrosion and neglect, and the latter is almost pardonable when one considers the dark, dirty, inaccessible holes in which air-pumps are so often placed. Corrosion is to be expected, and should be circumvented by putting neither bolts, nuts, screws, rings, valves, nor guards inside the pump. There are both vertical and horizontal air-pumps on the market which can be made without a single fastening inside. If you must use the old-fashioned vertical pump, put no rings in the bucket; water-sealed buckets need not be tight. I have known two plain buckets ¾ in. less diameter than the pumps in which they worked to give 10 lb. vacuum in the cylinder.

Secure the bucket and guard against a collar or cone on the bottom of the rod by a nut or cotter on top, as in Figs. 1 and 2, instead of tapering the cone downwards and putting the nut below the bucket, as in Fig. 3, where it will drop off and allow the bucket to fall into the foot-box. Slide the foot-valve grid into grooves in the foot-box, and cast the guard upon the foot-box cover, as in Fig. 4, so that there may be no bolt to corrode and break. If the pump be horizontal, the bucket will not be water-sealed, and the piston must either be renewed when it has worn down, or fitted with a ring. The piston, being a plain disc, can be screwed and shrunk on to the rod.

Do not use combinations of brass and iron. If the water be at all acid, a brass-sheathed rod will be cut through, where the sheathing ends, as with a knife. Avoid trunk motions. The screw of the eye at the bottom of the trunk will suffer from corrosion, and the pin from grit. Every trunk motion I have had to deal with has broken down at least once. Finally, pay great attention to all fastenings; put the air-pump in a light, accessible place, and if there be any doubt about the free flow of the water from the hot-well by gravitation, make the motion fit for a pressure of at least 50 lbs. per sq. in. on the bucket.



FIGS. 1 TO 6. AIR PUMP VALVES AND BUCKETS AND BED-PLATE HOLDING DOWN FEATURES.

Bed Plates.

Breakages of engine-frames and bed-plates can be dismissed with a very few words, because by far the largest number are caused by the pounding of the engines or by wringing up holding-down bolts, after the seats below have been softened by oil. It is true that, with modern systems of lubrication, and oil recovery, very little oil should reach the seat, but it is equally true that the modern practice of wetting down an unplaned bed-plate in a rough lump of concrete, packing it level with any bits of iron that may be handy, and grouting it with cement, provides so little material to resist the oil that the grouting ceases to give adequate support even sooner than did the old ashlar seats with gallons of oil poured over them each week. The consequence is that breakages of frames, bed-plates, and the like still bear as large a proportion to the total breakdowns as in the early eighties—namely, about 7 per cent.

It is quite easy to keep engine-seats dry and free from oil. All frames and bed-plates should have channels round the feet, as in Fig. 6, and troughs under the ends of all bearings, or, when there is only a top and bottom brass, shields like those on the bearings for the shafts of dynamos and motors. The bed-plates of vertical engines of the marine type should have the bottom of the crank-pits cast with them.

Where a bed-plate is to rest on ashlar, it should be planed on the underside, and rubbed to a perfect fit upon the dressed surface of the stone. When it is to rest on concrete, the bottom surface which is to be supported by the cement grouting should be as wide as possible, instead of a strip a few inches wide along each side, and holes should be arranged at intervals for running the cement into the space between it and the concrete seat. In my opinion it is best to plane the underside at each holding-down bolt, and level the bed-plate upon a pair of broad machined folding-wedges at each bolt-hole, as in Figs. 5 and 6.

Cylinders should not be placed on concrete, but on iron frames or plating, according to their shape. This plating should have holes for running cement between it and the concrete seat, and there should be raised rims round these holes, round all openings for pipes and round the edges, to retain oil and water; also machined facings for the cylinder feet to stand on, so that they may slide when the cylinder end should be free to slide. Never tighten a holding-down bolt till the superincumbent weight has been lifted from the bed-plate, and the space below it, if there be any, carefully packed.

Cylinders.

In old days, breakages of cylinders were generally due to water or stray piston-bolts; now the majority are caused by water or structural weakness. The diagram, Fig. 7, shows plainly what has happened. The abscissae represent successive periods of five years from 1879 to 1913, and the ordinates the breakages of cylinders, as percentages of the total number of breakdowns, in each quinquennial period. The year 1883 may be considered as about the end of the old time, when 80 lbs. was a high pressure, and a tallow kettle simmered on the cylinder. About 1890 steam of 160 lbs. pressure began to be used in mills, and many old cylinders, reduced in diameter by liners, were supplied with it regardless of weakness of ends and valve-chests. Also, many of the new cylinders made about that time were too weak. The curve shows how breakages increased, and subsequently decreased as the new conditions were met by improved designs.

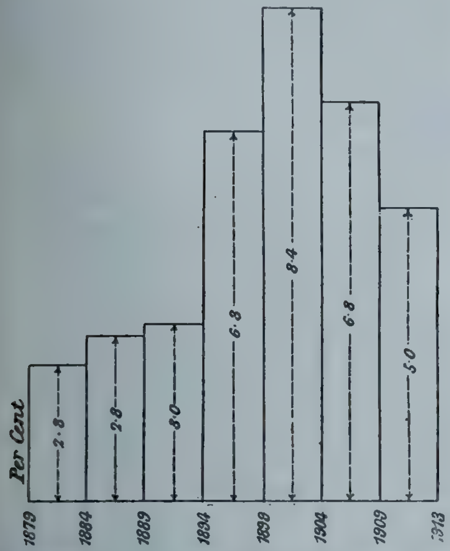


FIG. 7. CYLINDER BREAKDOWNS PER CENT. OF TOTAL BREAKDOWNS.

Before referring to some of the faults of design which provoke fracture, I would like to remind designers of cylinders and other parts that deformation, or strain, induces stress. It is often an advantage to consider what deformation would occur in the thing they may be designing if it were made of india-rubber. Figs. 8 and 9 show a cylinder made in 1894 for a pressure of 120 lbs. per sq. in. It worked for eight years at that pressure, then for 18 months at 140 lbs., and finally for six months at 160 lbs., when the two longitudinal cracks (A) (A), Figs. 8 and 9, were found.

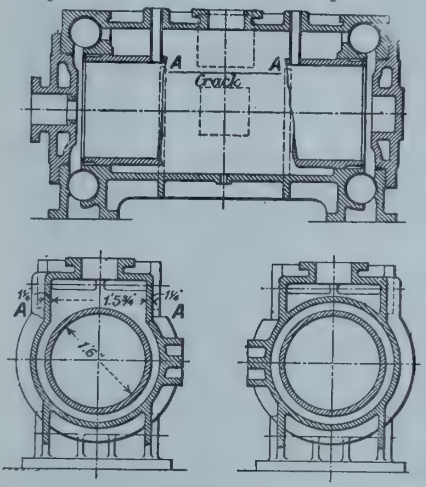
Regarding the cylinder as made of india-rubber, it would be seen at once that the two sides of the upper part of the jacket, Fig. 9, would be forced outwards, and bending would occur just where the cracks appeared. Even if the outer cylinder were complete, as in Fig. 10, the steam-passage would be a source of weakness, because its bottom surface, having the same pressure on both sides, would flatten out and allow the same kind of deformation as before. The flat top of the steam-passage, Fig. 9, was also weak, and would probably have cracked along its longest edges in course of time, for the stress calculated by the formula for flat surfaces—

$$t = p \times \frac{b^2}{2t^2} \times \frac{l^4}{l^4+b^4}$$

given in Unwin's "Machine Design" was 16,000 per sq. in.

In good designs, I have found (f) to lie between 3,000 lbs. and 8,000 lbs. The wide variation is not surprising when one considers how much the strength of castings is affected by shape and crystallization during cooling. In dealing with castings, experience is the only safe guide, though, for purposes of comparison, a formula may be useful as a rough criterion.

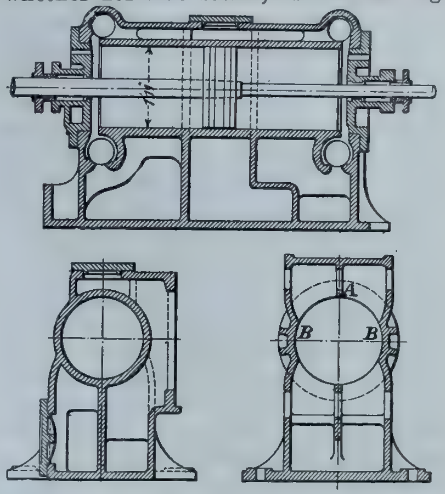
Figs. 11 to 13 show the high-pressure cylinder of a triple-expansion engine, made five or six years later, for a boiler pressure of 160 lbs., and a pressure of 70 lbs. in the receiver between it and the I.P. cylinder. Soon after it was set to work, it cracked through the bars across the ports (A) Fig. 13, and then from the corners (B) of the ports. It was replaced by another of the same design, which quickly failed in the same way. Here there was a load upon the end of 92 tons during admission and 52 tons during exhaust.



FIGS. 8, 9, 10. STEAM CYLINDER FEATURES.

If the cylinder had been rigid and the load distributed uniformly over the cross-section of the metal, the stress would nowhere have been excessive; but, with a cylinder of india-rubber, it is easy to see how a large part of the load would be concentrated on the bars across the ports, and how, on their failure, the deformation of the end would intensify the stresses at the corners of the ports. Also, deformation of the barrel from a circular to an oval cylinder would be caused by the external pressure on the top and bottom, and the absence of an equal external pressure on the sides. This deformation is sometimes sufficient to make well-fitting pistons seize.

Finally, passages cast round cylinders, whether for live steam, as in these figures, or for exhaust, frequently originate circumferential cracks in the barrel, owing to the unequal expansion of the metal inside and outside them. They are also likely to cause sponginess where the walls join on to the barrel. The design is not one to be copied, and I cannot but suspect that if the draughtsman had kept the india-rubber model in mind when he was drawing it, these cylinders would never have been cast.



FIGS. 11, 12, 13. STEAM CYLINDER FEATURES.

The usual way of strengthening the ends of cylinders is to lengthen the distance between the ports and the end flanges, and then to lengthen the spigots on the cylinder-covers to fill the increased clearance spaces. Unfortunately, the clearance surface at each end of the cylinder is thereby increased by two rings, each equal in area to the circumference of the cylinder multiplied by the length of the spigot—rather an important disadvantage when saturated steam is to be used, and guarantees of steam consumption are required.

Of course, it is possible to suppress the surface by making the spigots fit the cylinder, but then it is extremely difficult to get the cover off; or by making the joint at the surface of the spigot next the piston, but that may be as dangerous to the cylinder and cover flanges as a ring of jointing material placed entirely inside the bolt circle, unless special precautons, which I cannot now describe, be taken. The practical alternative seems to be to make the space so narrow that, when it is filled with water, the surface of the water presented to the steam in the cylinder will be so small that the condensation and evaporation will be negligible.

The late Mr. Bryan Donkin made some experiments for me to determine how narrow the space would have to be, and he told me that, under most conditions, differences of 1-16 in. in the diameter of cylinder and spigot would probaly suffice to keep the space filled with water and the surface inactive. His experiments were made with clean steam. With oily steam the space might possibly be increased, because the fluid filling it would be more viscous than pure water.

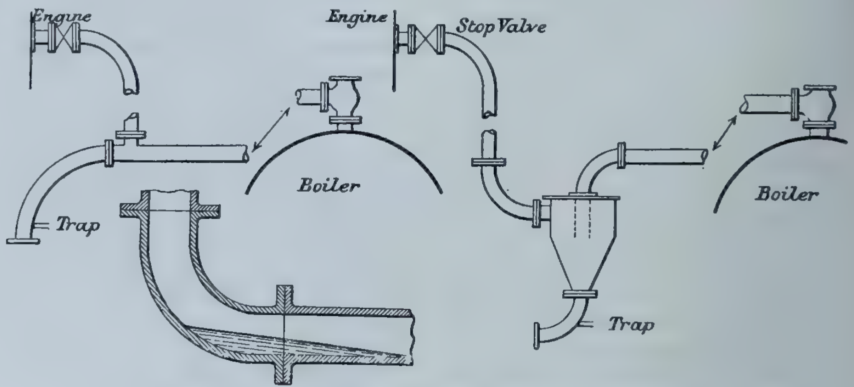
If the bell-mouth and spigot be bored and turned slightly conical and to fit each other when there is no jointing material between the flanges, then, when the jointing material is put in, the water space will be very narrow, but will widen rapidly as the cover is being drawn off. When the bell-mouth is very short, deformation, and local stress at the corners of the ports, may be reduced by bolting a deep cover, like a short cylinder with its two flanges tied together by ribs between the bolt holes, to the cylinder flanges.

The difficulty of designing cylinders for high pressures, and temperatures is much enhanced by attempting to combine valve-chest, steam and exhaust passages and cylinder in a single casting. It is far better to make cylinders plain tubes, or plain tubes with nozzles near the ends, and to carry the valves in suitable gable ends, with cylinder-covers or valve-chests bolted to the flanges on the barrels. The arrangement allows the barrel to be made of hard metal, giving an index number of about 40 when tested by Shore's scleroscope; while the more complicated castings, containing barrel, valve-chests, and passages, cannot be made with metal, giving a higher number than about 36. Moreover, the distortions produced by temperature and by the growth of grey cast-irons under temperatures as low as 500 deg. Fahr., imperatively demand the very simplest forms.

Damage by Water.

Leaving cylinder design, I now wish to say a few words about breakdowns from water. Water is seldom carried over from boilers in sufficient quantity to cause damage when steam-pipes are properly laid, as shown in Figs. 14 and 15, with a continuous fall from the boiler junction valve to a well-pipe or separator to the engine stop-valve, which should be at the highest point of the pipe, and as near to the cylinder as possible. Pipes with vertical bends, Fig. 16, are apt to harbor water when only a light breeze of steam is blowing through them, and this water is carried forward in gulps when the breeze becomes a hurricane. Even these gulps, however, seldom do damage, except when they get into the upper ends of vertical cylinders, the exhaust ports of which are shut before the end of the up stroke, or into horizontal cylinders with the exhaust-ports on the top.

Generally, the water causing breakdowns comes from jet-condensers, when an engine is running slowly, and the injection cock has not been shut, or the vacuum destroyed. The flow into a jet-condenser depends upon the vacuum therein, the flow out of it upon the speed of the air-pump; and it may easily happen, when an air-pump is running slowly, that more water may enter the condenser than the air-pump can discharge, in which case the excess first fills the exhaust-pipe and then runs into the cylinder. For this reason, when the air-pump is driven by the main engine, the vacuum should always be destroyed by letting air into the condenser before beginning to shut off steam; and when it is driven by an independent engine, this engine should be started before, and stopped after, the main engine. It is often extremely interesting to discover how water has got into a cylinder, but time will not permit of going into this point now in further detail.



FIGS. 14, 15, 16. STEAM PIPE ARRANGEMENTS.

SMOKEBOX CINDERS AS FUEL.

IN the Zeitschr. des Ver. Deutsch. Ingen, Mr. O. Nerger emphasizes the importance of utilizing locomotive cinders for heating purposes, and describes the various plans put forward up to the present to do so. Experiments with chain grates and other mechanical methods of stoking have not been entirely successful. The management of the Royal Breslau Railway Co., which is building a new head workshop at Oels, has recently engaged in exhaustive researches on this subject. At the suggestion of Mr. Cohn, the Government engineer, these researches were extended to the forced draught traveling grate Pluto stoker, because it had already been found possible with this device to burn up profitably coke cinders, anthracite dust, and other non-gasing fuels of that nature.

Its chief element consists of a hollow grate piece which is movable to and fro, and is provided with slots on its inner or heated surface. Compressed air enters the furnace through these slots, pre-heating the air, and preventing any lowering of the general temperature of the furnace. In earlier trials, the cinders showed a tendency to cake together in spite of the motion of the hollow grate, and so their passage over the slots was impeded. The caking of the cinders also stopped up the slots and hindered the entrance of air. Thus the cinders were not completely consumed and a considerable proportion of unburned materials was found in the residues.

A number of slight modifications, such as regulating the speed and throw of the grates and the pressure of the air, remedied these defects, but the chief improvement consisted in introducing steam into the hollow grate bars as it loosened the clinkers and allowed the air to have free access to the furnace. The success of the arrangement is due to the continual loosening of the fuel by the to-and-fro motion of the bars, thus giving the air of combustion access to all parts of the fuel.

◆

Valve Setting Data Wanted.—R. W., Ottawa, Ont., wishes some information relative to "Valve Setting," also some pointers covering procedure to be adopted in cases of emergency due to valve trouble.

If our correspondent would be a little more definite in his query and let subscribers to The Power House know the particular type of engine he is operating; the construction of its valve feature, whether slide piston or Corliss valve fitted, etc., there will be, we are sure, no lack of helpful instructive replies forthcoming from the pens of our readers.—Editor.

Power Plant Equipment, Rolph & Clark Ltd., Toronto, Ont.

Staff Article

In all lines of manufacturing there is in evidence a desire when plant extensions or additions have to be undertaken to so lay out and equip the various departments, that not only will a higher degree product be the outcome, but a healthy, wholesome and comfortable condition of operating will be the lot of the employees. With this ideal in view, power, light, heat and ventilating provisions are indispensable. The accompanying article features these in the plant under review.

ROLPH & CLARK LTD., Toronto, recently started operations at their new lithographing plant which is the largest establishment of its kind in Canada. The building is of fireproof construction and consists of brick walls, steel columns and steel roof trusses, with the main floor of concrete. The offices are situated on a gallery or mezzanine floor at the front end of the structure and overlook the main or factory floor.

All the machines are driven by electric motors, there being over sixty of these installed throughout the factory. Direct current is used for the motors and other equipment, and in order to convert the a.c. current from the Toronto hydro-electric lines to d.c., a motor-generator set has been installed. The motor generator set and switchboard are located in a room at the rear end of the building and on the main floor. This room is enclosed on two sides by glass screens with metal frames and on the other sides, the walls are faced with white glazed bricks. Artificial illumination is provided by a semi-indirect lighting fixture.

Electric Installation.

The motor-generator set consists of a 100 k.w. 110-125 volt, a.c., interpole generator, direct connected, on a common bed plate, to a 145 h.p. induction motor, 3 phase, 550 volts, 25 cycles, 450 r.p.m. The switchboard is of Blue Vermont marble and contains 4 panels equipped with the usual instruments and switches. There is one motor-generator panel, one d.c. generator panel and two feeder panels. At the back of the switchboard, and underneath it are two 20 k.w. lighting transformers, 550 volts primary and 110 volts secondary. These are for the lighting circuit when the motor-generator set is not required to be running, or in the event of an overload, in which case the current would be taken direct from the outside feeders and delivered at 110 volts to the lighting circuit. The motor-generator set, switchboard and transformers, were supplied by the Canadian Westinghouse Co., Hamilton, Ont., and were installed by the O'Connor Electric Co., Toronto, who also carried out the entire electrical installation.

Boiler Installation.

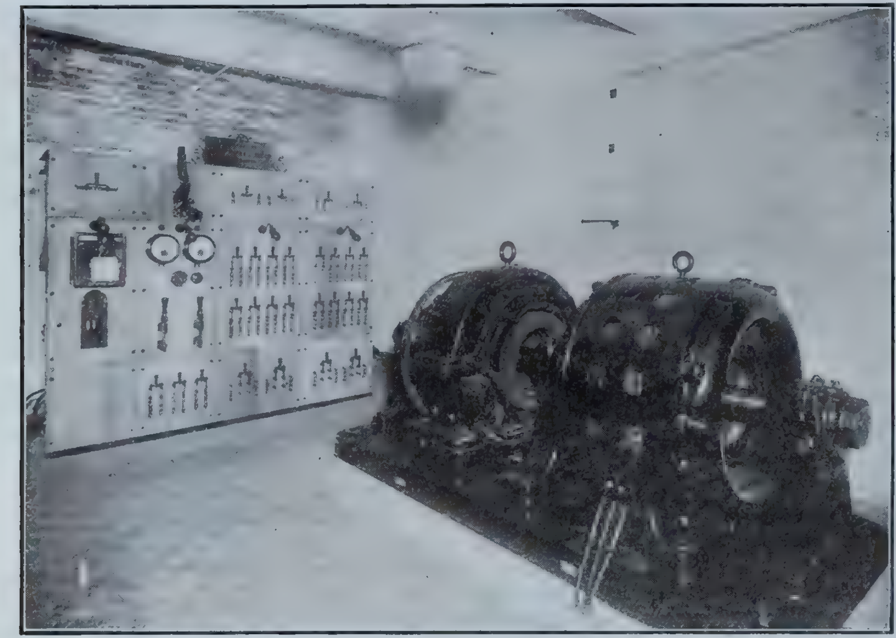
The boiler room is situated at the rear end of the building and at a lower level than the main floor. The pumps and heating and ventilating plant are located in the boiler room, the pumps being on the boiler room floor and the air washer and heater on a gallery above the pumps.

The boilers are two in number and are of the horizontal return tubular type, 78 in. by 18 ft., containing 1800 sq. ft. of heating surface and rated at 150 h.p. each. They are set in the standard suspension setting at centres 7 ft. 11 in. apart, and were built and installed by the Berg Machinery Mfg. Co., Ltd., Toronto.

Stoker Installation.

Two stokers have been installed under these boilers of the Fulton water-cooled type, manufactured by the Hare Engineering Co., Ltd., Toronto, and contain 36.7 sq. ft. of grate surface each. This gives a ratio of heating surface to grate surface of 49:1 which is sufficient to admit of heavy overloads being carried whenever required. These stokers are of the inclined front feed type, the coal being fed from a hopper which extends across the whole front of the stoker and from which it is fed down on the grates by the pushers. The grates are made up of broad flat cast iron plates extending across the width of the stoker and arranged in two separate banks, one of which is fixed to the frame of the machine, while the other is connected at the front end with a revolving eccentric which causes the grates in the moving bank to have an elliptical motion, and thus the coal is gradually pushed down over the inclined grates while being consumed. By the movement of the fuel thus secured, it is impossible for the coal to slide on the grates, thus air holes in the fire are prevented, while by the construction of the grate bars themselves, sifting of unburned coal through to the ashpit is avoided. The grate bars of this stoker are water protected by 1¼ in. extra strong seamless tubing being cast in each grate and connected to carry water circulation from the boiler. By the introduction of special check valves in this tubing, a flash system of circulation is set up which gives a high velocity of steam and water in the tubes and thus prevents accumulation of scale. It is claimed for this system that grate bar repairs are practically eliminated.

The stokers are operated by a 3 in. by 3 in. vertical engine running at 175 r.p.m. and back geared through enclosed cut spur gearing to the stoker drive shaft. The power required to drive the stokers is about one-third of one per cent of the steam generated, and in a recent test these two stokers were operated with only 7 lbs. of steam. Each stoker is driven from the common driving shaft by an independent ratchet and, in this way, can be driven at any desired rate of capacity independent of one another. This is found to be a decided advantage where a number of stokers are driven from a single engine. The successful operation of the plant was put to a severe test during the recent cold weather and although the thermometer registered 20 deg. F. below zero, no difficulty was experienced in carrying the load on one boiler and stoker, even though this represented a considerable increase over normal.



MOTOR GENERATOR SET AND SWITCHBOARD.

The draft is secured by a Heine radial brick chimney 119 ft. 6 in. high by 50 ins. inside diameter. It was built by the Heine Chimney Co., Chicago, Ill.

Pump Installation.

The boiler feed pump is of the horizontal duplex type, 4½—2¾—4 in., and is fitted with brass valves, seats and stems and brass linings to the cylinders. There are two vacuum pumps installed in connection with the heating system. These are of the horizontal single steam driven type, 6-8-12 in., and are fitted with Tobin bronze rods, brass lined glands and cylinder linings. A "Kiely" regulator is fitted in the return line from the heating system and the feed pump is equipped with a "Mueller" pump governor. All returns from the heating system go to a common header and are pumped to a receiver, then back to the boilers. The pumping installation was supplied by the Deane Steam Pump Co., Holyoke, Mass.

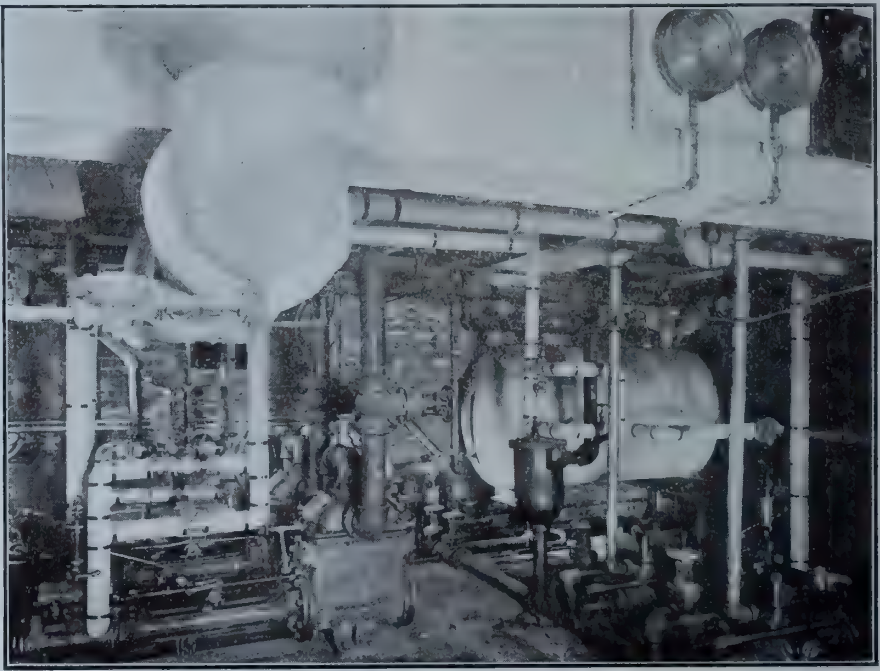
Heating and Ventilating System.

The building is heated by a low pressure steam system, but there is installed for ventilating purposes a heating and ventilating system in addition. This apparatus consists of a "Vents" tempering coil and a reheater containing a total heating surface of 2600 sq. ft. Between the heaters there is an "Acme" air washer consisting of a series of eliminators and spray heads which are flushed automatically and controlled by an automatic device connected to a centrifugal pump on the boiler room floor. The pump is driven by a 3 h.p.C.G.E. motor running at 1100 r.p.m. Under the spray heads is a tank which, when full, automatically drains into a sump where the pump just referred to is located.

In connection with the above, there is installed a Canadian Sirocco full-housed single inlet fan having a capacity of 40,000 cubic ft. per minute when running at a speed of 172 r.p.m. The fan is belt driven by a 20 h.p. motor, the speed being controlled by a Cutler Hammer speed regulator. The air washing and heating apparatus was supplied by the Thomas & Smith Co., Chicago, through Francis Hankin & Co., Toronto, and the fan by the Canadian Sirocco Co., Ltd., Windsor, Ont.

A "Powers" temperature regulating system is installed in connection with the heating system. Diaphragm valves are fitted to the tempering coils and the reheating coils. These valves are each controlled by a thermostat set to operate at 50 and 70 degrees F. respectively, the control being effected by means of compressed air supplied at 15 pounds pressure by a belt-driven compressor. There is also a thermostat fitted to the hot water service tank, set at 160 degrees F., and operated by city water pressure. The temperature regulating system was supplied and installed by the Canadian Powers Regulating Co., Toronto.

The lay-out of the mechanical plant was designed by the James A. McAlear & Co., consulting engineers, Chicago and Toronto, and carried out under the supervision of Mr. Melvern Thomas, the Canadian manager.



BOILER FEED AND VACUUM PUMPS.

Forced Versus Natural Draft for Steam Boilers

By J. B. Mayhew

This article formed the subject of a paper read before the Oklahoma Ice Manufacturers' Association, and in its contents sets forth the many advantages to be obtained through having a forced draft equipment fitted to steam boilers for all classes of service; the chief feature being immunity from weather vagaries.

IT is the custom the world over to use cheap fuel for firing steam boilers, a proceeding to which no objection need be made, provided that the principles which govern the efficient combustion of the fuel are practised. These principles teach us that quick combustion increases temperature. While the total amount of heat produced by the complete oxidation of a pound of carbon may be the same, whether the process is slow or rapid, the temperature is very much higher when quick combustion takes place. The heat given off by a slow cooking fire is much less than the same fuel under a blast This fact can be realized when it is considered that the rate at which heat is conducted through the plates or tubes of a boiler is in direct proportion to the difference in temperature between the flue gases and the water, and it naturally follows that the higher initial temperature of the gases, the greater will be the absorption of heat by the water. With strong draft, it is possible to use thick fires, which enables fuller use to be made of the oxygen passing through the fuel bed, and in consequence, the amount of air furnished per pound of coal, is diminished. This reduction in quantity of air is very beneficial, the result being that less heat is carried off by the stack to warm up the outside atmosphere.

Furnace Air Supply.

Experiments in the United States Navy demonstrated that in the hand-fired furnace, with stack draft, twice the theoretical amount of air was required, or twenty-four pounds of air per pound of bituminous coal, and it will be found, by analyzing the flue gases of the average plant, that two or three times the above amount is being used.

The temperature of combustion of soft coal with the theoretical air supply (11.75 pounds air per pound of coal) is approximately 5,000 deg. F. With 18 pounds of air per pound of coal, this being the amount furnished by forced draft, the combustion temperature is around 3,500 deg. F.; and with 24 pounds of air per pound of coal, as required by natural draft, it is about 2,700 deg. F. In the majority of furnaces, however, with natural draft, the excess air is so great that if a pyrometer were used the furnace would not show more than 1,800 deg. to 2,000 deg. F. The interchange of heat between the boiler and gases being proportional to the difference in temperature, it can readily be seen that this is an item of importannce.

Strangely enough, the greater the excess of air, the higher will be the temperature of the outgoing gases, and less heat is absorbed by the water in the boiler. This is accounted for by the total volume of the gases passing through and around the boiler and tubes being increased, thus causing swifter travel, and in consequence, less heat is imparted to the water in the boiler, and the amount of interchange of heat is proportional to the time of contact.

In a majority of cases, plants having a limited range of fuels and well meant attempts to realize economy by using cheaper coal, are prevented by lack of draft. A sure indication of insufficient draft is the ash pile outside the boiler-house, which remains in a glow for hours and sometimes burns for days. In cases of this kind, surprising reductions can be made in the coal bill by improving the draft or increasing the grate area, although the latter gives more excess air. The best thing to do is to use more draft and get a hotter fire. Low-grade coal can be burned by using extremely high stacks or by mechanical draft, but with the exception of tall city buildings, where chimneys are, as a matter of course, carried to considerable heights, few boilers are provided with stacks high enough to create sufficient draft for its proper combustion.

The draft required for efficient combustion of any fuel is the suction or pressure needed to cause sufficient air to flow through the coal, and is chiefly dependent upon the size of the fuel. It therefore follows that the smaller the fuel particles, the greater should be the draft, due to friction caused by forcing air through the coal. Any required intensity of draft can be produced by a stack, as it is only a question of going to a suitable height and keeping the gases hot enough. The chief objections to a high stack as a draft producer are its absolute lack of flexibility under varying load conditions and the impossibility of increasing its capacity to keep step with the demand of a growing business, and its great ability to pull in air through boiler walls and draw gases over the surface of the boiler so fast that it is impossible to absorb the heat generated from the fuel.

Forced Draft Advantages.

The advantages of mechanical, or forced, draft are many, though largely dependent upon one another. The points of superiority of forced draft produced by fans, as compared with chimney draft, are as follows:—

Low first cost.
Small operating expense.
Cheap fuel.
Increased and improved combustion.
Smaller boiler plant.
More thorough utilization of waste gases.
Absolute independence of atmospheric conditions.
Better regulation.
Economy of space.
Smoke prevention.
Greater adaptability, and best of all,
A balanced condition of air on the boiler walls.

Cost Comparisons.

The larger the plant, the greater is the proportional difference in cost of a stack, as compared with mechanical draft. Comparison of a number of average plants show that fan draft with engine and short stack cost about 25 per cent. of chimney. For small plants where each boiler has its own stack of light iron, it is about an even break on first cost, but the results you get are far better, for the stack will not do the work for which it is intended. The cost of operating the fan engine does not amount to anything, as the steam can go to the condensers or heating system. With forced draft, fuel of lower grade or poorer quality can be burned. To many plants, the change has brought a saving of more than 40 per cent. in the fuel cost, and it is very poor work if it does not save 25 per cent. It improves combustion, making it possible to burn 50 per cent. more fuel per square foot of grate area and run your plant easily where it has been a drag before, and increases the boiler evaporating capacity 50 per cent. by getting the hotter fire.

Forced Draft and Weather Conditions.

Forced draft is absolutely independent of weather conditions. When days are hot and still, the plant with its short stack and natural draft cannot hold steam if the coal is bad, while if you have forced draft, you speed up the engine and there it is. The man firing a furnace with natural draft, which is the result of two columns of air or gas at unequal temperatures and weights endeavoring to equalize or balance, fights his fire and wonders when the weather will change so that he can get enough draft to hold steam. Natural draft is also affected by wind, and everything dependent upon such variable elements as atmospheric temperature and wind must suffer in the matter of uniform results. I have seen 25 per cent. variations in natural draft by sudden changes in the atmosphere.

Let me draw you a picture of a plant with the average boiler and setting, and a stack of 85 feet high. The fireman has been burning good nut coal and getting along very well, but the manager finds that his fuel bill is eating up the profits. His coal dealer informs him that he can sell him slack from the same mine for half of what he is paying for the nut coal, and they try it. In spring, when the air is cool, things go tolerably well; but July and August come along with not a cloud in the sky and there is not the sign of a breeze. The smoke goes 200 feet high before it breaks, and it looks as if someone would have to shovel it from the top of the stack. What is the trouble? The fuel has the heat units in it, for analysis show that; but it won't burn, and why? Simply because the atmospheric conditions have changed, and the two columns of air or gas are so nearly balanced that the draft will not force enough air through the bed of the fine coal to furnish enough oxygen to burn it, and the gases are leaving the stack in the form of carbon monoxide gas. A pound of carbon burned under these conditions only produces 4,400 B. t. u.'s, and what the fireman does not burn he wheels out to the ash pile. What the poor fellow needs is a blower under his grates so that he can force the air through his fine coal and get the oxygen to burn the carbon to a carbon dioxide gas which is formed by burning one pound of carbon with two pounds of oxygen. This produces 14,500 B. t. u.'s, eliminates the smoke, produces steam, and is capable of such regulation as to accommodate itself to both fuel and weather vagaries.

◆

Cleaning Producer Gas.—The cleaning of producer gas by straining it through a porous diaphragm of fine-spun glass was recently described before the American Society of Mechanical Engineers in a paper by Mr. H. F. Smith. Both gas and tar pass through the diaphragm, but in passing, the tar particles coalesce into large drops which cannot be carried along with the gas current. By means of this process any desired degree of gas cleanness can be secured. Water or other washing fluid is not required, and the process is not one of filtration.

Buying Coal on a Systematic and Scientific Basis

By Hugh Lamont

Concurrent with other steps being taken to improve and keep in the forefront, steam as the motive power in our manufacturing and general industrial enterprises, the question of a suitable and uniform quality supply of fuel in the shape of coal is receiving closer attention. In this article are indicated various considerations which contribute to make a careful study highly profitable to the consumer.

THE generation of electrical energy from our waterfalls, and its distribution at cost, through our provincial and municipal governments, has done much to popularize the utilization of electric power in various manufactures, where steam had heretofore been the source of energy. Not a few instances of the discarded steam boiler has been the result, and where the steam boiler has not been discarded, there has been a general "toning up of the system," as it were, resulting in the adoption of the latest and best appliances for increasing the efficiency of the boiler. In other words, the manufacturer who depends on steam for his power has been and is endeavoring to utilize to its fullest extent the heat units stored in his fuel, which is usually coal. In this he has been ably seconded by the fuel engineer, the manufacturer of boilers, the manufacturer of stokers; in fact, by the manufacturer of all kinds of accessories that have for their aim the minimization of losses in the generation and transformation of energy.

Everything that is being done is done with a view to the elimination of losses in the power plant; but the loss annually occurring through unbusinesslike methods of buying coal is one to which the average consumer of this country has given little thought. Practically everything the manufacturer buys is bought under a guarantee of some kind; but when it comes to buying coal, he still continues to buy on the basis of its looks or its general reputation, though it is a self-evident fact that, in order to get the highest efficiency in the power plant, it is first necessary to have efficient methods for the selection and purchase of our source of energy, namely—coal.

Constituents of Coal.

A proximate analysis tells us that coal consists of moisture, volatile matter, fixed carbon, ash and sulphur, and, according to the proportions of these component parts, we have coal varying from the highest grade anthracites through the different grades of semi-anthracite, semi-bituminous, bituminous, down to the lignites.

Moisture in coal is partly due to the moisture existing in the coal as mined, and is partly due to conditions of the weather during transit. At any rate, it has no heating value; but it is there in all coals, and in percentages over which the shipper has no control.

Volatile matter consists of carbon, hydrogen, oxygen, and nitrogen in varying percentages, and is given off as gases during the first stages of combustion. As some of these gases are inert, the heating value of the volatile matter is a variable quantity.

Fixed carbon is the chief source of energy in coal, as the process of combustion consists mainly in the burning of this carbon, together with the carbon and hydrogen of the volatile matter, and with the oxygen of the air introduced through the draft.

Ash is the residue left after all the combustible matter has been burned out of the coal, and consists of silicia, alumina, iron oxide and sulphide, sulphate of lime, magnesia, etc. Coals having ash high in sulphide of iron and fusible alkalies have a tendency to form a slag, which often adheres strongly to the grates, thus seriously interfering with the draft, and are more to be feared on this account than a coal where the ash is high in silica and alumina. Coals having a high percentage of ash are, as a rule, more difficult of combustion under ordinary conditions, than the lower ash coals.

Sulphur exists in coal as iron pyrites, sulphate of lime and as free sulphur. Free sulphur burns readily and has a heating value, though disagreeable odor, but, where found in combination with iron and lime, its tendency is to form a slag as noted above.

Calorimetric Test.

From the foregoing we have a knowledge of the component parts of coal as represented by a proximate analysis, but on account of the variable factor introduced by the volatile matter, an analysis of this description does not always represent the relative heating values of different coals tested in this way. As the heating value of a coal really represents the available energy stored therein, it follows that a comparison of different coals should really be made on a basis of their heating values. This can only be done by a calorimetric test, which consists in burning a weighed portion of the coal in a metallic bomb immersed in a measured quantity of water, and noting the rise in temperature of the water due to the combustion of the coal. The heating value of the coal, thus determined, is expressed as so many British thermal units, (B.t.u.) per pound of coal. By comparing the heating values found by calorimetric tests on various coals with the results of proximate analysis, we often find that coals, of apparently the same analysis, will vary considerably in heat units. This variation is due, as noted before, to the volatile matter.

In the selection of a coal, the consumer has also to take into consideration the adaptability of the coal to his furnace conditions. To determine this factor tests for furnace efficiency should be conducted under actual working conditions. The number of pounds of ashes removed for every hundred pounds of coal fired, taken in conjunction with the percentage of ash as determined by laboratory tests, will give a basis for comparison of the relative adaptability of coals thus tested. For instance: suppose a certain coal shows by laboratory tests ash of 10% value, which would mean that 90% was combustible matter; and that, from the fires, there was removed 25 pounds of ashes for every 100 pounds of coal fired. It would show that instead of burning 90% of the coal, we are actually only burning 75%, and 15% of the combustible matter is carted away in the ash and clinker. It follows that the nearer we approach the 100% mark on these tests the more adaptable the coal is to furnace conditions. In actual practice, an approach within three per cent. is considered good.

Specification Covering Supply.

Having determined by test the kind of coal that may be burned successfully in any given plant, it is important to the consumer that this standard of coal be delivered at all times, and specifications covering same should be made part of the contract under which he buys his year's supply. It is important also that the specifications be so drawn that it will be to the interest of the dealer to carry out his part of the transaction. In specifying the heating value of coal as a basis of a guarantee, the contract should be so drawn that all coal deliveries are paid for on the actual heat units contained in the dry coal. This automatic system of regulating penalties and bonuses is arranged for by specifying in the contract, the net B.T.U. to be delivered for one cent, thus:—

Suppose the contract calls for coal containing 14,000 B.t.u. per pound, at a price per ton of $1.90. This means that for every ton of coal delivered, the consumer is to receive 28,000,000 B.t.u. (14,000 × 2,000), for which he agrees to pay $1.90, or, for every cent expended, he is to receive 147,368 B.t.u. (28,000,000 ÷ 190c.). This then is the basis of the contract and all coal delivered thereunder should be carefully sampled and the B.t.u. value determined by calorimetric test, and all coal represented by each sample should be paid for in accordance with the heating value found.

For instance, suppose a sample represents 100 tons of coal, guaranteed as above. Actual tests, however, show that the coal contains but 13,800 B.t.u. per pound, or (13,800 × 2,000), 27,600,000 B.t.u. per ton. As the contract calls for 147,368 B.t.u. for one cent, the 100 ton unit, as mentioned above, is worth only (27,600,000 ÷ 147,368), 187 cents, or $1.87 per ton, the price which should be paid. Suppose, on the other hand, however, that the coal delivered shows by test a value of 14,200 B.t.u. per pound or (14,200 × 2,000), 28,400,000 B.t.u. per ton, then, as the dealer only agrees to deliver 147,368 B.t.u. for one cent, the value of each ton in this case becomes (28,400,000 ÷ 147,368), 193 cents or $1.93, the settling price.

It has been pointed out that, with one exception, the heating value of a coal represents its money value. The exception is in the ash. The higher the ash, the more difficult it is to burn out the combustible matter, and the reduction in price, in accordance with the calorimetric test, does not make up to the consumer the loss in furnace efficiency and added expense for removal of excessive ash content. It follows then, that there should be a limit placed on the per cent. of ash allowable, and some provision made for the rejection of coals exceeding this limit, or for acceptance at a reduction in price greater than that due to the B.t.u. This precaution is necessary to prevent the substitution of inferior grades where it has been demonstrated that a high grade coal is an absolute necessity in obtaining good furnace efficiency.

The consumer will likely find a reluctance on the part of the coal dealer toward a guarantee as specified herein, but, when thoroughly understood, a contract of this kind is eminently fair to both. It protects the dealer who is prepared to furnish high grade coal in competition with dealers handling inferior coals at the same price. It encourages him to deliver coal above contract grades by providing a premium for all coal thus delivered, and, on the other hand, the consumer will find it to his advantage to pay a premium of the extra heating value delivered.

This plan has proven successful in many localities, and will prove itself satisfactory wherever the specifications are carefully drawn, and the consumer and dealer alike, have a knowledge of the basic principles that tend to make for efficiency in the coal pile.

READER, WHAT DO YOU KNOW?

Among readers of The Power House there is a clearly defined sincerity of desire to know how each overcomes the daily problems arising out of the care and operation of the power plant. It is believed that your methods of solving these are valuable, and can be made more so, if you publish them, so that other brains may help in the work. We will provide the setting and pay you for the material. When your fellow engineer puts the super-structure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

PROBLEM OF THE THRUST BEARING.

HENRY T. NEWBIGIN in a recent paper read before the Institution of Civil Engineers, drew attention to the inefficiency of thrust bearings as compared with journal bearings and their disadvantages, especially in high-speed machinery. A comparison was made between Coulomb's laws of friction and the late Professor Osborne Reynolds's hydrodynamic theory of lubrication, and coefficients of friction in bearings of various forms were given, while the way in which the friction in a journal bearing changes from dry or greasy friction to perfect lubrication as the speed increases was also discussed. The late Beauchamp Tower's discovery of liquid pressure in the oil-film was described.

Viscosity was defined, and the resultting general formula compared with the results of Mr. Tower's and Professor Goodman's experiments. The conditions necessary for the maintenance of liquid pressure in an oil-film were also examined and defined.

The subsequent developments of Reynolds's hydrodynamic theory of lubrication were referred to, and A. G. M. Michell's formulae for the resistance of lubricated plane surfaces were cited: the paper concluding with description, illustrations and the results of tests of thrust bearings constructed on Michell's principle.

Winnipeg, Man.—It is announced that the Winnipeg Electric Railway will undertake extensive hydro-electric developments. Plans are being prepared by the J. G. White Corporation, New York.

REFRIGERATION DEPARTMENT

ABSORPTION AND COMPRESSION MACHINES.*

By C. Braungart, Jun.

WE distinguish to-day between two systems of mechanical refrigeration—the compression system and the absorption system. I will not here describe the mechanical and physical points wherein these two systems differ from each other, but will rather discuss the question of knowing how to select wisely between them—i.e., when to install an absorption and when to install a compression plant.

It is not, as is often stated to-day, a question of the one system or the other being pre-eminently the best under any and all conditions. Much too freely claims of this character are being made by advocates of the compression system, and again by absorption machine enthusiasts. Too often a poor compression plant is compared with a good absorption plant, to the detriment of the former, or a poor absorption plant by contrast with a good compression plant is made the cause of erroneous conclusions. Because a plant of a certain type is a pronounced success in a particular locality or installation, it is no criterion that the same combination of parts, or a duplicate plant, will be equally successful for you.

Determining Factors.

The determination of the question, "which is the best type of plant to install," under given conditions, is not an easy one, and requires for its solution proper consideration of many intricate problems. First and foremost, of course, there is the water supply. This may be good, or bad in quality, plentiful or scarce in quantity, and cheap or costly to handle. Then there is the question of fuel or power, with all its possible variations; and last, there is the question of the size of the plant, character of the anticipated ice business, and quality of ice desired.

These different considerations, with their infinite complexities, make absurd the claim that there is only one type, or system, that will work out best under such an astounding variation of conditions as we can present to ourselves. This is the very reason why to-day our largest machine manufacturers are building and offering machines of different types. It is because they realize that, under certain conditions, one or the other type of machine will give better results.

Compression System More Flexible.

There can be no argument, I hold, on the statement that of the two systems the compression system is the more flexible. It can be adapted to a more varying combination of conditions than can the absorption system. This is at once apparent when we consider that the absorption machine must have steam power, while the compression machine is not dependent upon steam power, but may be operated electrically or in any other manner. Furthermore, under varying loads the compression machine can be more readily handled and adjusted, merely because it is more flexible and also because there is no such intimate chemical relationship between the component parts as with the absorption machine.

On the other hand, there may be many places where an absorption machine would fit in to best advantage, notably, where very low temperatures are desired, or in connection with existing industries that have available exhaust steam for use in the generator; but in such case, the water conditions must not be such as would entail a high steam pressure, causing high back pressure on the main plant, which could very readily produce a condition in which the combined operation would be very uneconomical. It is a recognized fact that absorption plants require more cooling water than compression plants. Therefore, should the cooling water be scarce, one should hesitate to install an absorption machine, unless other conditions were greatly in its favor. Neither should one install a low pressure, or so-called exhaust steam absorption machine where the water supply is very high in temperature, for the temperature of the water, as it governs the condenser temperature, also controls the steam pressure under which the ammonia generator operates, and the higher the water temperature, the higher the steam pressure, and the less the economy.

The Economy Feature.

Furthermore, I desire to state most emphatically that the best plant is not always the plant that makes the cheapest ice, or the most ice per ton of coal. To elaborate, suppose you were favored with a fuel supply which was extremely cheap, it would be far better to install a simple plant making fewer tons of ice than an elaborate plant, making a high return in ice per ton of coal, for the very simple reason that the interest, depreciation and fixed charges on the extra cost of the expensive plant would more than offset the saving in coal. This is the very point I wish to drive home; viz., that the economy of the plant, as usually stated in tons of ice per ton of coal, should be worked back into dollars and cents, and referred to the total investment of the plant, and the probable factor of the plant.

It will then show quite frequently that a cheaper plant, making less ice per ton of coal, is a better investment than an expensive plant. In fact, it is possible to conceive a situation in which the purchase of the most expensive and most economical machinery, from a coal consumption standpoint, is the very death knell of what would otherwise be a remunerative business venture.

Where after due consideration of all the questions, it is decided to install a high efficiency ice plant, what we all dreamily refer to as a 10 to 1 plant, do not make the mistake of thinking this increased economy is going to be all profit. Whether you install a compression or an absorption machine, in either case you will have to have an evaporation plant of more or less complexity, which will not, I assure you, simplify your plant, or make it cost less. Both the compression and the absorption machines have been brought to a very high state of development by manufacturers whose aim is always to produce plants that are money-makers for their owners, for that is good business on their part, and with either system it is possible to-day to bring the fuel cost per ton of ice to a very low figure, so that the selection of which type of machine to install should be left, in the last analysis, only to some one who is fully competent to decide on this important point.

The determination of this question is really the field of the consulting engineer, for it cannot, obviously, be expected of the purchaser and plant owner that he acquire all the figures and data necessary to a proper solution of the problem. The employment of competent advice will in nearly every case be reimbursed, and will save many losses and disappointments.

OIL ENGINES FOR ICE PLANTS.

SPEAKING before the Eastern Ice Association on the subject of motive power for ice plants, Mr. Price, of the De la Vergne Machine Co., New York, said that one of the greatest advantages of electric power or electricity for the production of motive power has been the elimination of the labor. By putting in an electric motor, we can dispense with the fireman or the attendant at the producer; but with an ice plant this labor charge, with electric power, will be just as much for an electrically driven plant as it will for an oil engine driven plant.

The Saving Claimed.

It is possible with the latest type of oil engines to manufacture ice at a fuel cost of 14 to 20 cents a ton, and with oil at 3½ cents a gallon, such as can be purchased now from a number of different Oil Companies, the De La Vergne Co. is prepared to guarantee 17 cents per ton for ice, and have a number of plants accomplishing this. With electric power at 1 cent per kilowatt hour, it costs 61 cents per ton of ice. Seventeen cents a ton with the oil engine will effect a saving for motive power of 44 cents a ton. Take the case of the 200 ton ice plant, that would mean 80 dollars per day, or, if the plant should run 250 days per year, there would be $23,000 difference in cost of power for the year.

You may say that the item of depreciation has not been taken into account, but if you can put in a prime mover for $40,000, that will save you $22,000 a year, where does the depreciation and interest enter into it? In less than two years' time, the cost of the installation will be entirely wiped out, and after that time there will be a saving of $22,000 a year.

Typical Installations.

We recently contracted for four 280 h.p. oil engines, two of 100 h.p., and one of 140 h.p., for one ice plant, in N. Y. City, and also for two 280 h.p. and two 100 h.p. engines for another plant in New York City, and we have made such guarantees that on the 3½ cent oil basis, the price of oil to-day, the cost of fuel for ice will be 17 cents per ton.

We have the American Ice Co.'s installation at Philadelphia, which consists of an 18 in. by 38 in. compressor and a 230 h.p. oil engine connected by rope drive to the compressor, and, as a unit to furnish the power for the auxiliaries, a 100 h.p. engine to furnish the power for the alternator. It is large enough to drive a plant of twice the capacity. In Washington we have a 280 h.p. engine connected by rope drive direct to the 18 in. by 38 in. compressor, and also a generator belted from the main shaft, so that in the cooler seasons the one unit will furnish all the power for compressors and auxiliaries. When the heavy season comes on, the 100 h.p. engine furnishes the power for the alternator and the air blowers. There is, however, no saving in the use of an internal combustion engine over a steam engine if ice is to be made from distilled water. In order to reap the benefit of using internal combustion engines, it is necessary to make raw water ice, either by the plate process or raw water can process, and the oil engine, we think, has the advantage over the steam unit and the producer gas outfit, of eliminating the entire attendance charge and of requiring for fuel cost not more than one-quarter what the steam plant requires and not more than one-fifth of what is required by electric power.

WHO'S WHO.

ELECTRIC POWER FOR ICE CREAM FACTORIES.

A PREFERENCE for electric power to that of steam in ice factories was the opinion expressed by Mr. Grubbmeyer at a meeting of the Maryland Ice Cream Manufacturers' Association, recently. He said every proposition in which refrigeration is involved has three considerations, which we should have to settle in order to apply our proposition, and get the best out of it at the least expense and lowest operating cost. The first is the engineering aspect as evolved under the proper selection of apparatus. The second is the question of power, and the last consideration is the motive possibilities, and the financial state of the proposition.

Under the engineering possibilities, we have the question of the amount of refrigeration which is required to accomplish our purposes, and at the present day this is pretty well settled as to what sized machine to put in. The question of layout is an important feature, and every part of the system should have consideration to get the most satisfactory results. The motors should be of a correct size in order that the losses be low and the efficiency be high. In the last few years the electrical proposition has been making headway, and the results accomplished are encouraging. With the electric system, the cost of the installation is lower than with a steam plant, the refrigerating part of the proposition involving an investment in some cases of about 50 per cent. of what steam would cost. Steam, of course, requires large water capacity and much room.

Operation Feature.

The first cost of the installation feature I have touched upon is for the refrigerating apparatus. The other part of the subject is the cost of the power to operate. In the operation of ice cream plants, the power is mostly used in the summer time. The power used in summer runs double what it does in the winter, and in some cases three or four times more. The power is sold at a higher rate in the winter. This means that the ice cream man can buy his power at a much lower cost than other manufacturing establishments using the same power throughout the year or more of it in the winter time. When you consider what this means, it seems to me that the electric drive has the steam proposition beaten out on operating cost.

Another factor connected with electric power is space. The amount of space required for the electric plant is much less, in some cases perhaps one-half. Then, again, we have to consider the question of heat, and in a large installation where steam is employed, the boiler capacity required is probably one-fourth of what would be required under the steam system alone.

OUR CIRCULATION DEPARTMENT.

ATTENTION is drawn to the fact that the circulation department of this journal is in charge of Mr. J. I. Coddington, Ph.B., to whom all correspondence relating to non-receipt of any issue by subscribers, advertisers, etc., should be promptly sent. By so doing, the editorial department will not only be relieved considerably, but a more immediate rectifying of the trouble will be brought about.

EDITORIAL COMPLAINTS AND CRITICISMS.

OCCASIONALLY we are recipients of a complaint or criticism relative to editorial matter published, but for the most part these reach us in a more or less roundabout, indirect, and therefore, unsatisfactory manner; to wit, they rarely come direct. Let us say at once that we are not only at your service in the most direct manner possible to receive complaint and criticism, but lay claim as well to an average mortal's courtesy. Further, it is a common, every-day experience outside of the editorial feature of technical journalism, to find that an indirect approach contributes either to a distortion of facts or to an increase of fiction, or both; a set of circumstances not originally intended.

Bless you, no, we are neither infallible nor stubborn, nor are we in any sense unapproachable and inclined to aloofness. Let us get closer together then by eliminating the middleman, and you, The Power House and we ourselves will be all the better for it.

THE ATTRIBUTE OF HONESTY.

SOME time ago, a contemporary drew attention to the revelations concerning the New York, New Haven and Hartford, and the Boston and Maine Railroads, and expressed the opinion that, while enforced honesty by means of legislation was not only undesirable, but impossible, there was need of more effective measures than those now in vogue to make the crooked walk straight. Not a day passes, but the business and commercial life of this and every other continent is besmirched through the lack and practice of simple honesty by men in high places. In the humbler walks of life we are more or less prone to expect a considerable display of dishonesty, but just why, in this particular feature, none of us may be able to give a reasonably intelligent answer.

The dishonesty that is rampant in high places is becoming so common and brazen that it passes for smartness, and in a certain sense it earns the latter title so long as the malpractices remain undiscovered. The stress of keen competition in any and every sphere of the activities of our being contributes largely to the practice of dishonesty in a variety of form, and as this determination to get ahead of the other fellow is growing in intensity all the time, the outlook seems not altogether one for decrease, but rather increase. Referring again to the New Haven railroad, we have the declaration of a high official of the Government, following a careful investigation of conditions that "the powers that were did everything except run a railroad."

Education, philosophy and cultivation of intelligence are not only now within the reach of all who care to avail themselves of their acquirement, but are in addition being appropriated and effectively applied in the testing of men and things material, and only the lack of the most elementary intelligence on the part of a large percentage of men in high places, or a surfeit of avarice blinds them to the fact that they are being shadowed by the detectives of public opinion. In politics and affairs municipal, votes are paid for directly and indirectly, and in too many industrial and other corporations, the prosperity of the financier, and not the commercial interests of his community or his country, much less the welfare of the employees is the sole ideal. Is it surprising, therefore, when the names of some public men are mentioned that suggestions of honesty—plain, simple, downright honesty, are ridiculed?

Finance enters into all enterprise as a necessity, but finance, it is too often forgotten, is but a means to an end, and not that end. How often, however, do we find it both the means and the end, and the latter in more ways than one. Many industrial enterprises would still have been in existence had high finance not crushed them out, and many of those which to-day are wobbly would have been firmly established and flourishing had the like sinister influence not been allowed to usurp the real purpose of their being. Legislation, however drastic, will never make men honest, if for no other reason than the fact that those who legislate for us come far short of infallibility with respect to wisdom, justice and even common-sense. It may be said in reply that our rulers are but a reflection of ourselves, but this is only true in part, for it cannot be said with honesty of conviction that they are so representative.

Business enterprises, if run as purely financial institutions, are a menace to the progress and development of any country, and affect unfavorably the welfare of its citizens, besides courting ultimate ruin for those directly interested. In support of this statement, we don't have to cast around very much or very far for convincing proof. Much has been written relative to the display of earnest, honest, whole-hearted effort on the part of employees, but little is to be found which calls for honest business methods and administration on the part of those to whom this duty and privilege has been given.

* * *

MISPLACED CREDIT.

WE read the other day of the triumph of a certain city over a public utility corporation doing business within its borders, in the matter of a point of law relative to the privileges granted to and the conditions to be observed by the latter. Credit, of course, was generally given the city's representative in the person of its legal luminary for the successful outcome of the court proceedings. It transpires however, that other and at least equally zealous champions of the city's welfare had carefully scouted the battle ground of the opposing party, and had so trained their guns and developed their plan of attack that in any case victory was inevitable. In other words, the opposing party hadn't a leg to stand upon in their contention, therefore, consummate forensic ability counted for little in the successful result.

We are inclined to think that there is a strong tendency in every sphere of enterprise and endeavor to misplace credit—a failure "to give honor to whom honor is due." It seems to be part of our general make-up to conclude that he is the hero who bears away the spoils of victory, and that they who blaze the trail are but insignificant conveniences and, therefore, of no account. We are so superficially intelligent as to be unable to discern otherwise, and, may we add, so stupidly content, as to desire to remain so. In every sphere of human endeavor and enterprise, social, commercial, industrial, political and religious we give credit to individuals in a collective or unit capacity for compassing some scheme for the general moral uplift, for the completion of some great railroad or transportation undertaking, for the inauguration of some movement which makes for the welfare and safety of workpeople in our factories, for the stand on some question of national policy by a political party which a more or less selfish interest most probably instigated, and for the unification of Christendom by the adoption of one creed and one set of doctrines, yet, are oblivious, the while, to the fact that we and many others also took a part in the game.

Some people would have us believe that to-day in commercial and industrial enterprise "the race is to the swift and the battle to the strong only." Those who dispense this line of wisdom are, however, either of the silver-spooned birth variety or of the semi-invalid type, who have never known what it is to earn a living or who have had a hand-picked portion placed at their disposal by some interested spirit. The misplacing of credit is both a crime and a curse, robbing as it does the deserving of their birthright and bringing ultimate discredit and ruin on its originators and the recipients. The oft quoted statement that "there is honor among thieves" has no existence in fact, and never had, else we would have more honor to our credit as individuals, as a community, and as a nation, and have fewer thieves. In like manner if we properly allocated the credit due each individual either in his craft or in his citizenship, there would not only be a greater co-operation and unity of interest, but a disappearance of that suspicion of motive and enmity bred of distrust.

In all business enterprise there are to be found two classes of employees—the producers and the non-producers, and it goes without saying that the former get the credit, if that happen to be a feature, and the latter are either ignored or are reminded of their uselessness, although unfortunately necessary existence on the payroll. Diagramatically and by ofttimes reiterated address and writing we are informed that direct personal touch with and tab on all the employees of our large manufacturing concerns is kept and that a magnetic influence emanating from the peak of the organization draws worthy character and service thereto. We are also told, and examples are quoted and multiplied, of men who neither would nor could be kept down in their ambition to rise to high place, but we are without record of those who failed, not because of their lack of the qualities necessary, but purely on account of a misplacement and in many cases through the appropriation by others of the credit due them.

Only the other day, to quote an example dealing with a topic which is filling a large place in the Canadian political and industrial world at the present time, viz., the application for Government assistance by the C.N.R., there was being widely circulated the report that the C.P.R. was exerting its powerful influence to oppose the desired financial help. Rightly or wrongly the latter railroad management were being so credited, and only when the highly significant words of the C.P.R. president were given voice to "that it was not the C.P. (Canadian Pacific), but the **Canadian People** who were in opposition to a further grant to the C.N.R., was it apparent that here was another obvious case of misplaced credit. In this instance, it was a desire to save its face on the part of the Canadian people and its representative Government.

It exemplifies misplacing credit by blaming another, and differentiates only from that in which another's reward is purloined. The baneful effects are the same however, in each case.

TENSION ON CYLINDER COVER STUDS.

By J. H. Rodgers.

IN replying to A. E. W. on his solution to the problem of the Tension on Cylinder Cover Studs, I do not wish to enter into any heated argument in support of my solution, but wish to call his attention and also that of others to what, I believe, to be an error in his view of the question. By closer examination of the article in the February issue of **The Power House**, the tension of 1,005 lbs. under correction by A. E. W. will, I think, be found correct.

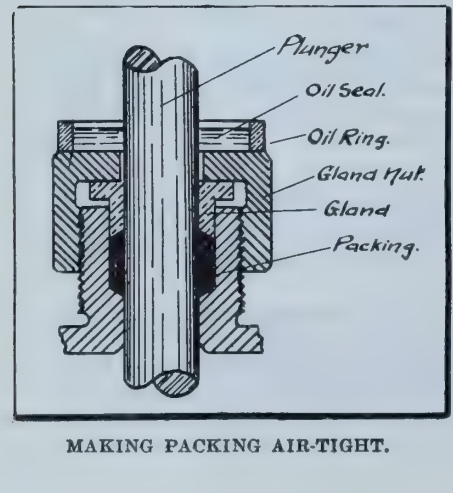
A. E. W. contends that, after the studs have been elongated 1-1000 of an inch, due to the initial tightening of the nut, an extra weight of 800 lbs. placed on the cover will put no additional stress on the studs, but if a weight of 2,000 lbs. is placed on the cover the studs will be elongated a further 1-1000 of an inch. Surely there has been some mistake in calculation, for why is it, that there is an elongation of 1-1000 of an inch between a weight of 800 lbs. and one of 2,000 lbs., and yet there is no elongation between 0 and 800 lbs?

* * *

MAKING PACKING AIR TIGHT.

By N. G. Near.

HAVE you ever had trouble keeping the packing of a hand pump perfectly air tight? Where the packing is leaky, you usually have a hard time making the pump "catch" without priming it. Here is a simple method for assuring air-tightness—make an oil-seal. An oil ring can be easily attached to the stuffing box cap by sweating on, or in a hundred other different ways; all that is necessary being to make the joint leakless. Pour in a fairly heavy lubricating oil, and as long as any of the latter remains in the cup you have thus fashioned, you may be assured that the packing is tight. If gasoline be the liquid pumped, lubricating oil will not harm it, in fact, lubricating oil is a good thing to mix with gasoline for use in connection with reciprocating gasoline engines.



MAKING PACKING AIR-TIGHT.

* * *

TENSION ON CYLINDER COVER STUDS.

By J. Roy Brodie.

IN the February issue of **The Power House**, there appears a question which I believe was up for discussion some years ago. Mr. Jones, who was the originator of the problem, thought there would be no increased tension on the studs till the steam cylinder pressure exceeded 100 lbs. per square inch. Now, if the above pressure causes increased strain, I cannot understand why any pressure lower would not have the same effect in proportion.

I do not consider it necessary to explain my theory with diagrams for the reason that I agree in every particular with the theory of Mr. J. H. Rodgers, but will add a little to his theory with the hope that it may aid in a more thorough explanation of the question before us. For instance, let us suppose the face plate was secured to the flange by studs having a tensile strength of 50,000 lbs. per square inch or sectional area, and if each bolt had a sectional area of a ½ square inch, the total strength of each bolt would be 25,000 lbs. With ten bolts, the total resistance to strain would be 25,000 × 10 = 250,000 lbs. The pressure exerted on each stud bolt by screwing up the nut being 1,000 lbs., therefore, on ten bolts the total pressure would be 10,000 lbs. The total pressure of steam on the face plate would be 100 sq. in. × 80 lbs. per sq. in. = 8,000. Deducting the combined effective forces of screwing up and total steam pressure on face plate—10,000 + 8,000 = 18,000 lbs., from 250,000, we get 232,000 lbs. excess strength of stud bolts.

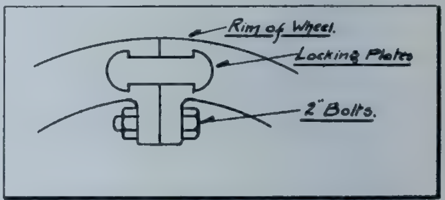
It is not reasonable to suppose that any pressure short of that required to elongate or fracture the stud bolts will lessen the screwing-up pressure. The tension on the stud bolts caused by the screwing-up strain is, therefore, constant, always tending to pull them apart or break them, whether live steam be in the cylinder or not. When steam at any pressure is admitted to the cylinder and comes in contact with the face plate or cover, the tensile strain on the stud bolts is increased proportionately, and is equal to the area of the face plate in square inch multiplied by the pressure per square inch. Now, the two forces as they affect the stud bolts act in the same direction, both causing a tensile strain outward, consequently they cannot balance each other, and, as there is nothing else to support this strain, the duty is fulfilled by the stud bolts, a conclusion about which there can be no doubt.

* * *

FLYWHEEL QUERY SOLUTION.

By "Centrifugal."

IN the February issue of **The Power House** there appeared at the foot of page 57 an enquiry from H. Westwood as to the stresses set up in the rim bolts and hub bolts of a flywheel 12 feet in diameter, running at 150 r.p.m. and weighing 10 tons. The hub and rim are



FLYWHEEL QUERY SOLUTION.

split, and the hub is held by four 2½-inch bolts, while the rim is secured by four 2-inch bolts. Mr. Westwood states that the initial stress in each of the hub bolts is 1,000 pounds and 700 pounds in each of the rim bolts.

Now, while I believe the following method of approaching this problem to be correct, I do not pretend to an expert knowledge, and hope some fellow-readers who are better up on the subject than myself will send along their solutions for publication.

Formula for Centrifugal Force.

The total centrifugal force (F) in a revolving body expressed in pounds is

$$F = \frac{W \times V^2}{g \times R}$$

Where F=Total centrifugal force in lbs.
W=Weight of revolving body in lbs.
V=Velocity of revolving body in feet per **second.**
R=Radius of gyration of the body in **feet.**
g=Acceleration due to gravity=32.2.

The radius of gyration (R) may be taken as the mean radius of the rim of the wheel. We are not told the size of the rim; but for the purposes of this solution let us assume that the rim is 10 inches deep. Then the mean diameter of the wheel will be

144 — 10 inches=134 inches.

and since R must be expressed in **feet,** we have

$$R = \frac{134}{2 \times 12} = \frac{67}{12} \text{ feet.}$$

Now, the force tending to disrupt a flywheel is not the total centrifugal force (F), but is (F) divided by 3.1416. The case is analogous to that of a boiler shell. Consider a certain length (1 inch long) of a section of a boiler. The total radial forces acting on this length are clearly found by multiplying the pressure of the steam in pounds per sq. inch by the circumference of the boiler in inches, or to put it into a formula:

Total force=P × 3.1416 × D.
Where P=Pressure per sq. inch.
D=Diameter of boiler in inches.

It is, however, well known that the force tending to rupture a boiler transversely is given by the expression, P × D. In other words, to find the force tending to burst the boiler, we divide the total pressure by 3.1416. Similarly in the case of a flywheel we must divide the total centrifugal force (F) by 3.1416 in order to find the force tending to rupture the wheel at its diameter. Thus, the formula becomes:

$$\text{Bursting tendency} = \frac{W \times V^2}{3.1416 \times g \times R}$$

In this formula V is the velocity in feet per second of the wheel at the mean radius of the rim (R). This radius we have assumed above to be 67 inches. The corresponding **diameter** is therefore

$$\frac{67 \times 2}{12} \text{ feet.}$$

This circle revolves at 150 revs. per minute, and its speed per **second,** therefore, is

$$\frac{3.1416 \times 67 \times 2 \times 150}{12 \times 60} = 88 \text{ ft. per sec.}$$

We are now in a position to fill in the numerical values in our formula, the values being as follows:—W=20,000; V=88; R=67÷12=5.68; g=32.2.

The force tending to disrupt one-half of the wheel from the other half is, therefore,

$$\frac{20{,}000 \times 88 \times 88}{3.1416 \times 32.2 \times 5.68} \text{ pounds.}$$

=269,607 pounds, or (say) 270,000 lbs.

Assuming that the bolts have U.S. standard threads, the area at the root of the thread will be 2,302 sq. inches for a 2-inch bolt, and 3.719 for a 2½-inch bolt. The total area of the eight bolts will, therefore, be a trifle over 24 square inches, and the stress per square inch of area will be

$$\frac{270{,}000}{24} = 11{,}250 \text{ pounds.}$$

Relative Considerations.

Of course, considerable assistance will be given to the rim bolts by locking plates shrunk into the rim on both sides as shown in the sketch; but even allowing for this, it is clear that the bolts are too highly stressed. The trouble is that in the problem, as stated, the speed of the wheel is too high. The speed of the extreme outside edge of the rim is over 94 feet per second. This would be all right for a solid wheel, but for a split wheel the speed should be considerably reduced. Probably 60 or 70 r.p.m. would be as fast as it would be safe to run a well designed split wheel 12 feet in diameter, if made of cast iron.

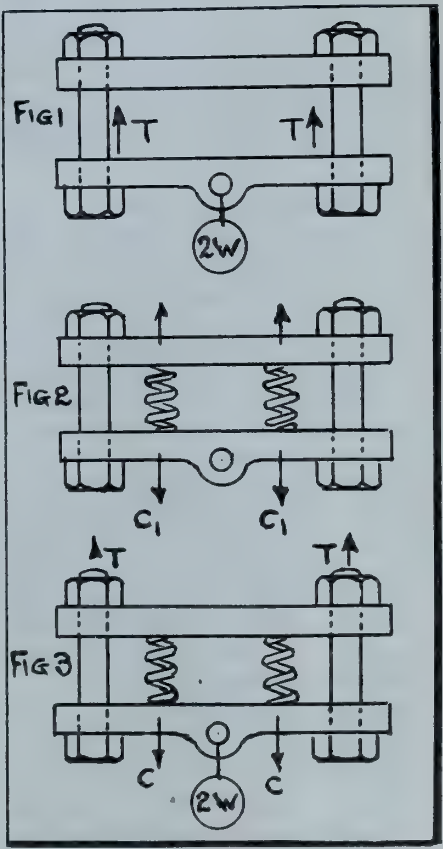
As the centrifugal force varies as the square of the velocity, it is obvious that a reduction of the speed to 70 r.p.m. would greatly reduce the bursting tendency, and consequently the stress in the bolts. The stress in the latter should not exceed about 3,000 lbs. per sq. inch of net section, for in addition to the tensile stress there is a shearing stress on the bolts. If we reduce the speed of the wheel to 75 r.p.m., we shall have cut the speed in half, and the centrifugal force will have been divided by 4. The stress on the bolts would then be only about 2,800 pounds per square inch, which would be in accordance with modern practice.

An objection may perhaps be raised by some readers that the above formula treats the whole weight of the wheel as being concentrated in the rim, and takes no account of the effect of the arms. This is, of course, true; but a complete and accurate treatment of the subject involves the use of higher mathematics, and the formula here given is the one generally employed. It gives a result quite accurate enough for practical purposes. When we consider the severe and entirely unknown stresses set up in the wheel by the cooling of the casting when it comes from the mould, it is obviously useless to figure out the centrifugal stress too closely. In wheels having a comparatively light rim, the bending stresses in the rim, due to the centrifugal force of the portions between two arms, may very possibly increase the calculated stress by 50 per cent.; hence it will be admitted that an approximation to the truth is all that can be looked for, or usefully employed.

TENSION ON CYLINDER COVER STUDS.

By A. E. W.

SINCE sending in my first contribution on this interesting subject for the Feby. issue, I have come across a solution by a well-known expert, whose conclusions will doubtless be of interest to my fellow-readers. The authority referred to is Professor



TENSION ON CYLINDER COVER STUDS.

Unwin, whose "Elements of Machine Design," is a widely used text-book on the subject. Doubtless many readers are familiar with the book; and if they will turn to page 182 of Volume I., they will find the matter gone into very fully. For the benefit of those who do not know the book, I have here extracted part of the chapter dealing with bolts and nuts, and have made a copy of the sketches accompanying the section.

Straining Action on Bolts.

Professor Unwin says:—"Suppose a plate be suspended by two bolts, and a load (2W) hung midway from it (Fig. 1). The tension on each bolt will be $T = W$, and the case presents no ambiguity. Commonly, however, the plates which are themselves to some extent elastic, are screwed tightly together, with a more or less compressible packing between them, and there is an initial tension in each bolt before the load is applied. This tension is balanced by the elastic reaction of the pieces fastened together. The case may be diagrammatically represented by imagining the plates rigid and elastic springs interposed, Fig. 2. Then the arrangement being symmetrical, each bolt has initially a tension, $(T = C_1)$, due to the compression of the springs by screwing up. Let a load (2W) be now applied, Fig. 3. The tension in the bolts will increase, they will stretch and so diminish the compression of the springs, and the tension in the bolts will have some value between (W) and $(W + C_1)$, depending on the relative elasticity of the bolts and springs.

"If (W) be increased till the stretch of the bolts is equal to the initial compression of the springs, (C) vanishes, and, for this or any greater load, the tension in each bolt will be $(T = W)$, as in Fig. 1. In most practical cases, however, the initial tension due to screwing up must be sufficient to prevent this, or there would be a sensible separation of the connected pieces.

"Let the extension of the bolts be (A) and the compression of the springs (B) per unit of load, then initially the compression of the springs is (BC_1). When the load is applied, the bolts stretch an amount $A\ (T - C_1)$, and the compression of the springs is equally diminished. Then,

$$BC = BC_1 - A\ (T - C_1)$$

$$C = C_1 - \frac{A}{B}\ (T - C_1)$$

$$T = W + C = W + C_1 - \frac{A}{B}\ (T - C_1)$$

$$= \frac{B}{B + A}\ W + C_1$$

"If the springs are very rigid compared with the bolts, as when the bolts connect two strong flanges, (B) is small compared with (A), and then $(T = C_1)$, or the initial stress due to screwing up **is not increased by adding the load.**

"If the extension of the bolts be equal to the compression of the springs per unit load, $(B = A)$, and then $(T = \frac{1}{2} W + C_1)$, and this case might occur when there is elastic packing to make a tight joint between strong flanges.

"Lastly, if the extension of the bolts be small compared with the compression of the springs $(T = W + C_1)$

"In the more ordinary cases, therefore, the load on the bolt depends chiefly on the strain put on initially in screwing up. Since workmen may exert considerable force in screwing up bolts, the strength of the latter must often be much more than would be necessary if the load only were considered."

From the above it will be noted that Professor Unwin states that the load does not increase the initial tension in the bolts when the heavy flanges are bolted together, as in the case of a cylinder cover **metal-to-metal joint.** Of course the stress in the bolts would be increased if the load exceeded the initial tension, but in such a case the joint would not remain tight.

Where an elastic packing is inserted in the joint, the load **does** increase the initial tension in the bolts, so that the two rules quoted in my first contribution would seem to hold good. In the accompanying figures, the upper bar is supposed to be fixed, the lower beam being suspended from it.

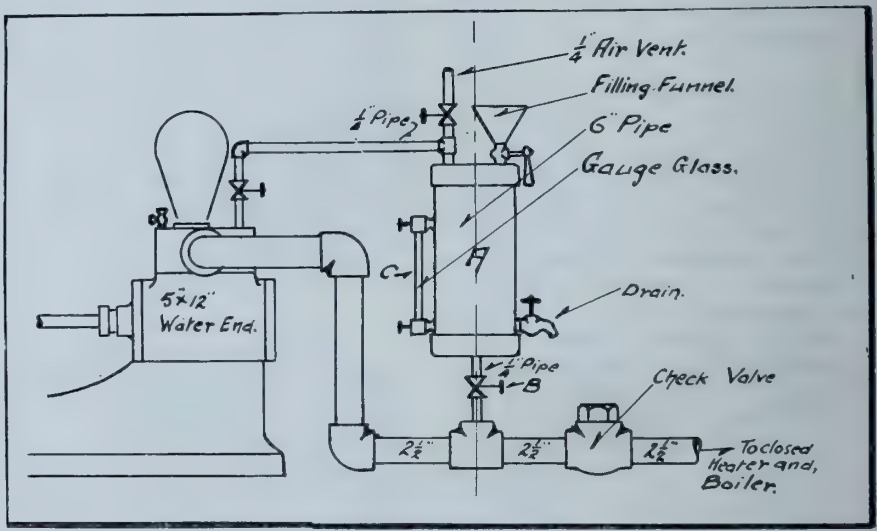
Discussions on subjects of this nature are certainly very interesting, as is clearly evidenced by the number of readers who are taking part in this one. I hope we shall have more of them.

A BOILER-COMPOUND FEEDER.

THE diagram herewith shows an interesting boiler--compound feeder devised by H. Mallinson, chief engineer at the Montreal Rolling Mills plant of the Steel Company of Canada. The principal advantage of this feeder lies in the fact that it delivers the compound to the discharge line, instead of to the suction line. When compound is drawn in with the suction, a certain amount of it is lost through leakage at the stuffing box gland. Moreover, the packing in an outside packed plunger pump is often rapidly destroyed by the compound, especially where a very strong mixture is used.

Referring to the sketch, at (A) is seen a piece of 6-inch pipe about 27 inches long and plugged at both ends. This is filled with boiler-compound through the funnel on top. Connection is made to the pump by a ¼-inch pipe as shown, the object of this pipe being to equalize the pressure above and below the compound. The latter thus gravitates into the feed line, the supply being regulated by the valve (B). As the compound descends in (A) it is, of course, automatically replaced by water through the pipe on top. The amount of compound remaining in the vessel (A) can be judged by the color of the liquid in the gauge glass (C). When (A) is full, the color is a dark brown, which gradually becomes lighter as the compound is replaced by the water. When the compound is all used up, the glass, of course, shows clear water. All valves are then closed and the water drained off. The air vent at the top is then opened and the vessel filled up again with compound.

This device has proved highly successful, and has been fitted to every feed pump in the Montreal Rolling Mills, as well as to a number in the other plants



A BOILER-COMPOUND FEEDER.

of the Steel Company of Canada. The size illustrated is used in connection with an 8-5-12 Simplex pump, but can easily be modified to suit larger or smaller units.

GAS ENGINE TROUBLES.

By W. M. Grey.

I WOULD like to have the opinion of some gas engineers as to causes of trouble which we have experienced lately at our plant. Installed are two vertical, four cylinder gas engines driving two belt-driven direct-current generators which run in parallel. At intervals, either one or other of the units will commence to pound, lose controlling power and close down. This happens in the short space of one minute. As pounding in the crank case often indicates a shortage of oil, we have kept the oil up to a good substantial level, and generally use one gallon per 8 hours on each engine. We run on the 24-hour system.

The engines are equipped with K.W. high-tension magnetos, which, including valves are apparently well timed. I have noticed that the generators do not parallel up very evenly. It may be that the equalizing wires behind the switch board are too small and if such be the case, would one generator have a tendency to motor the other, and throw the latter's engine out of step and cause pounding?

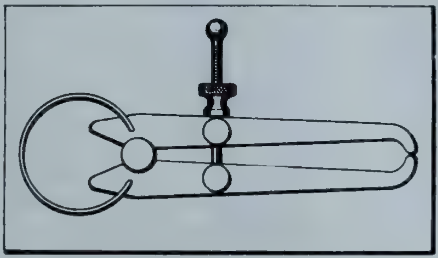
I have heard of several cases where vertical gas engines are in use and that they are consuming more oil than is really necessary. Makers of gas engines advise keeping the oil to a certain level; for which an oil indicator is placed in some convenient part of the engine frame. It very often happens, however, that the oil level cannot be ascertained, as the indicator glass is filled with a foam, due to the splashing which goes on in the crank case. I am of opinion that if makers of some of these high-speed gas engines would turn them out with an oil circulating device suitable to their particular type of product, it would be more satisfactory to themselves and also from the operator's viewpoint.

SPECIAL OUTSIDE CALIPERS.

By D. A. Hampson.

A HANDY caliper—one that every machinist should have—is that here illustrated. It is an "outside" spring caliper with straight legs and short points The writer has made a number of them from inside spring calipers by disassembling, filing notches on the opposite sides of the legs for the spring and the centre stud, and reassembling in reverse of their original position. A four-inch caliper is large enough for most of the work required of such a tool, and such a one converted would represent an outlay of about seventy-five cents and perhaps a half-hour's work. Many a time such a tool is worth twice that to a man who finds he has no tool in his kit that can be used for some certain job.

The uses of this caliper are many. For inspection purposes, it is particularly adapted. Assume that a small hole is to be drilled centrally in some rectangular blocks. How can its true location be determined? The anvil of a micrometer will not enter the hole. Outside calipers cannot be used—the big-bowed legs not permitting, while rivet joint inside calipers are too slow and too uncertain. The calipers shown are ideal for the task—sensitive, quickly changed and small enough ends to enter the hole so that any mechanic worthy of the name can detect a difference of .0015 in. between two measurements with them. On the planer and shaper they are very handy to measure the thickness of work being planed which is held in a vise or on parallels, but in such confined space (vertically) that bow calipers are out of the question.



SPECIAL OUTSIDE CALIPERS.

HEATING BUILDING USING CENTRAL STATION CURRENT.

By William Kavanagh.

THE installation of an electrically operated vacuum pump in conjunction with the heating system of a modern building using central station current for power and lighting purposes will lessen fuel expenses incurred during the heating season of each year.

The Vacuum System.

The most economical system of heating is known as the "vacuum system." Its installation involves the maximum cost, but its operation will be found to reduce heating expenses 25 per cent. over that of other known methods of steam heating. When the vacuum system of heating is properly installed, it will require the least amount of attention, and cost for maintenance will be reduced to the lowest possible degree. The employment of the electrically driven vacuum pump places the most economical system of heating within the range of any building not so equipped. The electrically operated vacuum pump has the great advantage of not requiring steam pressure for its operation, hence it can be seen that the pressure carried on the boilers may be reduced to that of the atmosphere; a desideratum tending towards economy of fuel.

Steam at atmospheric pressure has a sensible heat temperature of 212 degs. F., and a latent head capacity of 966 degs. F., therefore the total heat in 1 lb. of steam at atmospheric pressure will equal 1178 degs. F. If our system of heating is such as to rapidly convey away the water of condensation, and assuming the temperature of the returned water at 200 degs. F., then the total extraction of heat from 1 lb. of steam will equal 987 degs. F. From this we learn that all of the latent heat has become sensible heat by reason of condensation, and its useful effect has been realized in the heating of the building employing the vacuum method of heat circulation. In order to obtain such economy, it is absolutely necessary to have the radiators and piping free of air and water of condensation, but such a condition can only be had when the vacuum pump is employed.

Buildings equipped with the single and double pipe systems, warm air and forced circulation of hot water cannot approach in the matter of fuel economy those having the vacuum system installed. Incidentally, it should be mentioned that the attachment of the electrically operated vacuum pump to the pipe systems above mentioned will convert them into that of the vacuum system, involving only slight changes in the piping.

Vacuum System Advantages.

The vacuum system has many advantages over all other methods of steam heating, some of which may here be mentioned.

The low pressure carried on the boilers precludes all possibility of rupture or accident which are inherent in the systems using high pressure steam or forced water circulation.

In the vacuum system, the liability of leakage is remote; quietness of heat circulation is attained, and the heating effect is rapid, positive and equal over the entire plant. Such advantages are not within the scope of the other systems.

Miscellaneous Heating Systems.

The single pipe plan of heating is of two kinds, known as the "free" and "air valve" systems. In the free system, the air valve which is attached to the radiator is in turn connected to a pipe which is open to the atmosphere; the object being to facilitate heat circulation by permitting the entrapped air in the system together with the water of condensation to escape freely to the atmosphere. With the "closed or air valve" system, the air valve attached to the radiator is not connected to any other pipe, but is supposed to automatically perform the functions necessary to permit the steam to traverse the heater, and thus the dissipation of heat in the radiator is obtained.

The warm air system involves the use of a fan driven by some source of power. The fan discharges cool air through a bank of pipes containing steam, the warmed air being then conveyed through ducts conveniently located for the purpose of heat distribution.

Heating by means of warm water is accomplished in either one of two ways; one is known as "free circulation." With the other is that of "forced circulation." With the free circulation plan, advantage is taken of the gravity of the ascending and descending columns of water, thus obtaining an automatic circulation. With the forced circulation, a pump is used to circulate the heated water throughout the system, such circulation being continued as long as heat is required.

Heating by means of the electric current will materially reduce the cost, and more especially during the fall and spring months of each year. The electric current is extensively used for the heating of offices, baths, sleeping apartments, hospitals, etc., and when current can be obtained at a reasonably low figure, its continued use will be found to give satisfactory results owing to its adaptability to varying temperatures, non-vitiation of the atmosphere, cleanliness and simplicity of installation; all of which advantages combine to make it a superior media for the purpose.

From what has been said it can be seen that the maximum economy in the heating of a building cannot be obtained when fuel must be burned in order to force a circulation of steam through the heating system. Under the conditions where air can enter the piping and radiators and the water of condensation is not removed with sufficient rapidity, an unnecessary expenditure of fuel is required to overcome the resistance offered by the presence of these bodies. The employment of the electrically or steam driven vacuum pump eliminates such resistance and reduces the cost of fuel to the lowest possible degree.

KINK FOR PUTTING ON OVERALLS

By James E. Cooley.

EVERY workman knows that each time when putting on a pair of overalls the legs of the trousers become drawn up and have to be pulled down and smoothed out, as they feel uncomfortable when humped-up. A useful kink to prevent this, and shown in the illustration, is to fold the trouser-leg about the ankle and fasten with a bicycle-clip. The overalls will then slip on easy. The clip should be left on, as it prevents dust and dirt from getting up inside the trouser-leg

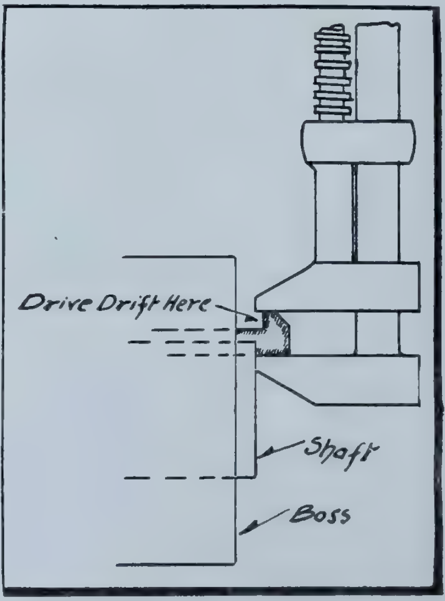
KINK FOR PUTTING ON OVERALLS.

◆

HOW TO PULL A TIGHT KEY.

By C. H. Lloyd.

I NOTICED in the February number of **The Power House** a kink sent in by N. G. Near, showing a method of pulling a tight key. This reminded me of a similar method which I have often used with success. Place a common monkey wrench on the head of the key, as shown in the sketch. Between the head of the key and the wrench drive a drift made of an old file tang or some other piece of steel, and steady the wrench with the hand, so that the key will not bend. The wrench holds the drift in place and prevents it flying out. It will be seen that the drift must not be thicker than the height of the head on the key. With this device it is possible to draw very stubborn keys without damage.



REMOVING A TIGHT KEY.

◆

Readers Queries

Horse Power Query.—To settle a little dispute between two engineers, an answer to the following query is desired: A car of 20,000 lbs. weight ascends an inclined plane of 8 deg. grade, 3½ miles long, in 15 minutes. If the friction be 3% of the load, what is the horse power absorbed?—C. Whyte.

Horse Power Query.—Frank Baker, Winnipeg, Man., requires the horse power of an Atlas Engine whose cylinder is 18½ inches diameter and 16 inches stroke; the r.p.m. being 190 per minute. Will our correspondent please furnish steam pressure, also cut-off if available?—Editor

Boiler Horse Power. — "Constant Reader" Edmonton, Alta., sends particulars of a 72 in. diameter by 18 ft. return tubular boiler, and wishes to know what are its respective horse-powers with working pressures of 125 and 100 lbs., per sq. inch. The information furnished includes thickness of heads and shell; number and pitch of tubes, but no diameter of same, although they are probably either 3½ or 4 inches diameter; grate area of 48 sq. ft.; diameter of safety valves 4 inches; shell riveting, head shell. It will be noted that much of the data here enumerated is unnecessary for the horse-power calculation. We are sure that a large number of our readers are in a position to fill this request, and in consequence look for a ready response.

Questions and Answers.—Our attention has been called to an error in the answer to question 9, on page 17 of the January issue of the Power House. A displacement of the decimal point in typesetting gave the answer as 16.83 horse power instead of 1.683 horse power.

◆

Question.—What force (P) will be required to raise a weight of half a ton by means of Weston's blocks when the compound pulleys have an effective radius of 3½ in. and 3¼ in. respectively; (1) when friction is neglected and (2) when the efficiency of the block is .35 per cent.?

Answer.—

$$(1) P = \frac{1120\ (3\tfrac{1}{2} - 3\tfrac{1}{4})}{2 \times 3\tfrac{1}{2}} = \frac{280}{7} = 40 \text{ lbs.}$$

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Attention is drawn to the concurrent course in arithmetic, a concurrent study of which is recommended with that of the Question and Answer Series.

Question—Should a valve in its travel open a full port to live steam?

Answer—No, because the ports are designed, so as to allow of a free escape of exhaust steam, and if a full port be given, or be necessary for live steam, then for exhaust, the port is not large enough.

* * *

Question—Why is it necessary to have a larger area of port for the exhaust, as compared with the live steam?

Answer—Because the live steam having done its work in the cylinder has fallen in pressure, and become naturally of greater volume, and requires a larger space or area for escape.

* * *

Question—What advantage has the Corliss valve and its arrangement on a steam engine over that of a slide or piston valve, and what are its disadvantages in comparison?

Answer.—It reduces the port clearance to a minimum, gives a practically full steam admission opening and sharp, clean, instantaneous cut-off; permits of water of condensation being drained off through the exhaust ports; is adaptable to close governing and gives independent exhaust valve adjustment. Its principal disadvantage is in the number of revolutions per minute; these being limited to 150 probably as a maximum, due to the uncertainty of the trip gear engaging and disengaging properly.

* * *

Question.—A railway train starting from rest along a level piece of track acquires a speed of 30 miles per hour in five minutes. What has been the **mean pull between the locomotive and the train,** if the resistance to motion is 10 lbs. per ton and the train weighs 225 tons. Take a ton as meaning 2,240 lbs.

Answer.—The constant pull due to resistances$=10\times225=2,250$ lbs.

Mass of train$=m=\dfrac{225\times2240}{32}=15,750.$

Velocity of train$=v=30$ m.p.h.$=\dfrac{30\times5280}{60\times60}=44$ ft. per second.

Momentum of train$=m\times v=15750\times44$, and time taken to produce this momentum$=5\times60=300$ seconds, therefore the mean pull producing change of motion is $\dfrac{15750\times44}{300}=2,310$ lbs., and the total mean pull between the engine and train is $2250+2310=4650$ lbs.

* * *

Question.—A screw jack has a screw of ½-inch pitch. If a force of 50 lbs. be applied at the end of a 36-inch lever and the efficiency of the jack is 40 per cent., what weight can be raised by it?

Answer.—Neglecting friction, the power put into the mechanism is equal to the power given out by it. That is to say, the force applied at the end of the lever multiplied by the circumference it describes in one revolution is equal to the pitch of the screw multiplied by the weight raised. In the present case, the efficiency is only 40 per cent., the other 60 per cent. being lost in friction. The weight actually raised by the jack will, therefore, be .40 of the weight theoretically raised. Calling the latter W lbs., we have

$W\times\frac{1}{2}$ in.$=70\times2\times36\times3.1416\times.40.$

$\dfrac{W}{2}=633.35.$

$W=1266.7$ lbs.

* * *

Question.—What is the distinction between **energy** and **power?**

Answer.—Energy is the capability of doing work which a body may possess by reason of its position, condition, or motion. It is of two kinds. Thus, there is **potential energy,** or that form of energy which a body possesses in virtue of its position or condition. For instance, when a pile driver drop weighing 50 lbs. has been raised 20 feet it has a potential energy of 1,000 ft. lbs.; for it takes that amount of work to lift the 20 lbs. through 20 feet; and, if then allowed to fall, the drop will naturally give out the same amount of work. An example of potential energy due to the condition of a body is found in the coil spring of a watch or clock.

e energy **due to** the motion of a body is called **kinetic energy.** For instance, in the first example cited above, the pile driver drop weighing 50 lbs., in falling freely through 20 feet, had stored up in it, due to its motion, an amount of work equivalent to 1,000 ft. lbs.

Power is the **rate** of doing work, or the work done in a given time. The unit of power in this country is the horsepower and is the rate of doing work, equivalent to 33,000 ft. lbs. per minute.

* * *

Question.—In a wheel and axle the radius (R) of the wheel is 20 in.; the radius (r) of the barrel is 4 in.; and the weight to be lifted is 300 lbs. Find the force (P) to be applied?

Answer.—P $\dfrac{300\times4}{20}=60$ lbs.

* * *

Question. — The crank or handle which turns a windlass is 14 in. long. What must be the diameter of the axle when a man exerting a force of 60 lbs. upon the handle raises a weight of 2 cwts.?

Answer.— $\dfrac{14\times2\times60}{112\times2}=7\frac{1}{2}$ in.

* * *

Question. — What weight may be raised by a block and tackle with three sheaves in each block, when the force (P) applied is 30 lbs.?

Answer. — $W = 30 \times 6 = 180$ lbs.

* * *

Question.—The two blocks (A) and (B) of a block and tackle weight 25 lbs. each, and the weight (W) is 200 lbs. The whole is held in equilibrium by a certain force (P) applied at the fall of the cord. What will be the pressure on the hook which supports the blocks?

Answer. — The total load to be raised $= 200 +$ weight of bottom block $= 200 + 25 = 225$ lbs. There are six cords, therefore, $P = \dfrac{225}{6} = 37\frac{1}{2}$ lbs.

The total load suspended on hook will consequently equal $200 + 25 + 25 + 37\frac{1}{2} = 287.5$ lbs.

* * *

Question. — The upper block of a rope and pulley lifting tackle has three pulleys, and the lower block has two pulleys. What force (P) in lbs. applied to the fall, will lift a weight of 4 cwt.?

Answer.—$P=\dfrac{4\times112}{5}=80\ 3/5$ lbs.

* * *

Question. — In a Weston's pulley block, the effective radii of the compound pulleys (i.e., from the centre of pulley to the centre of chain which passes round it) are 4 in. and 3½ in. respectively. Find what weight (W) can be lifted by a force of 20 lbs. (neglecting friction).

Answer.—

$W = \dfrac{2 \times 20 \times 4}{(4-3\frac{1}{2})} = \dfrac{160}{.5} = 320$ lbs.

Question.—The base of an inclined plane is 20 feet long, and the height 6 feet. Find the length (L) of the incline?

Answer.—L = 202 × 62= 20.88 feet.

* * *

Question.—The base of an inclined plane is 20 feet long and 6 feet high. What force (P) acting parallel to the plane will pull up a body weighing 300 lbs., when the co-efficient of friction between the body and the plane is .25?

Answer. — Work due to gravity = 300 × 6 = 1800 lbs. Work due to friction = 300 × .25 = 1500 ft. lbs. Total work = 1800 + 1500 =3300 ft. lbs. The length of incline is 20.88 feet, as above, therefore,

P = 3300 = 158.04 lbs.
———
20.88

* * *

Question.—A train of wagons weighing 80 tons is supported on an inclined plane rising one foot for every 60 feet of length, by a wire rope attached to a stationary winding engine. Find the tension on the rope?

Answer.—
Tension = 80 × 2240 × 1 = 2986.6 lbs.

SUPERHEATING STEAM IN LOCOMOTIVES.*

By Henry Fowler.

THE utilization of steam superheated, or of a higher temperature than saturated, has engaged the attention of engineers since the inception of the use of the expansive power of steam, i.e., since the middle of the eighteenth century. Its application in locomotives was suggested over 85 years ago, and for half a century many attempts were made to employ it in this class of engine. Owing to trouble arising from the packing and the lubrication, these were not successful, and the prominent position it occupies at the present day is very largely due to the investigations of Dr. Wilhelm Schmidt, of Cassel, and to the practical trials of his apparatus made by Mr. R. Garbe, of tthe Prussian State Railways. Various types of superheaters were tried, but the one now in most general use is that in which the steam receives its superheat when passing through small tubes placed in large smoke tubes through which the heated gases travel on their way from the firebox to the chimney. This type is general in England, where, in addition to the Schmidt system, the Swindon and Robinson systems, which differ from the Schmidt in detail only, are also employed. The utilization of the heat in smoke-box gases has been tried repeatedly, but without much practical success.

Under ordinary conditions, when an engine is running, the steam passing through the superheating elements carries away with it sufficient heat to keep the metal of the elements comparatively cool. When, however, a locomotive is running down an incline without steam, this does not occur, and it is necessary to prevent the gases from passing through the fire-tubes, which is effected by a damper or some other type of retarded. Arrangements are generally made for working the dampers or retarders automatically. The connection between the superheater elements and the header from which steam is distributed is a matter of importance, and the methods by which this is done constitute one of the chief differences between the various fire-tube superheaters. Essentially, however, they consist of those in which a joint is made between the pipe and the collector, and those in which the former is expanded into the latter.

Provision Against Trouble.

Piston-valves are employed almost exclusively in locomotives using superheated steam. These have to be of special design, owing to the greater fluidity of superheated steam and to the difficulty of efficiently lubricating any surface to which highly superheated steam has access and which has a heavily loaded machine-part passing over it. For the same reasons special attention has to be paid to the design of the piston-head. The high temperature of the steam necessitates glands of special design wherever they are required, as well as arrangements for cooling the glands by allowing access of air where possible. The packing used requires to be of special high-melting composition, and here, as elsewhere, it is necessary to design the parts so that as little pressure as possible exists between two surfaces which are exposed to the temperature of the highly-superheated steam. The oil used for lubrication is generally a mineral oil which has a high flash-point and which is fed into the various parts by a mechanical lubricator which will ensure a definite, determined amount of the lubricant being delivered regularly at the necessary points. The provision of a pyrometer which allows the engine-driver to know at what degree of superheat he is working is advisable. Owing to the use of piston-valves which do not permit the relief of compression or suction in the cylinders when running with the regulator shut, it is necessary to provide by-pass and vacuum relief valves. Some of these valves are also suitable for dealing with any water which may be carried over into the cylinders, whilst in other cases special relief valves are fitted. The large tubes in which the superheater elements are placed give little trouble.

The greater volume of superheated steam, when compared with saturated, has in many cases led to the adoption of larger cylinders and lower boiler-pressure. This leads to economy in boiler-repairs, which should counterbalance the increase of maintenance necessary for the extra apparatus required when superheated steam is used. The degree of superheat usually employed is 230 degrees to 260 degrees F. No figures at present seem to be available for the variation in the economy with varying degrees of superheat.

Chief Advantage.

The chief advantage claimed for the use of superheated steam in locomotives is the economy in coal-consumption, and on the Midland Railway, a number of trials have been made to ascertain what this is with the various types of engines, the comparison being made on the consumption per ton-mile under circumstances as nearly comparable as possible. These trials show that a saving of 23 per cent. in the coal consumption and of 22 per cent. in the quantity of water used, was obtained in one case, whilst in another, where the difference between the locomotives was solely in the superheater, the saving of coal was as high as 30 per cent. This high figure was probably due to the engine which used superheated steam having more reserve of power than the one employing saturated steam. From diagrams of these two engines it can be shown very clearly how much more fluid superheated steam is than saturated.

Experiments have been carried out to ascertain the effect of superheating the steam supplied to the high-pressure cylinder of a three-cylinder compound locomotive, and it has been found that a saving of coal of 25.9 per cent. and of water of 22.3 per cent. has resulted when comparison is made with a similar engine using saturated steam. In tests carried out with goods-engines, the coal-saving has been from 14.3 per cent. to 18 per cent.

Mechanical Stoking of Locomotives.—It was inevitable that when a satisfactory mechanical stoker for large locomotives was developed, it would have extended application. We understand that one large locomotive stoker Company has at the present time over 400 stokers in regular operation on locomotives in the United States, and that 200 of these are in use on the Baltimore & Ohio Railroad.

---

*From a paper read recently before the Institution of Civil Engineers.

Arithmetic for the Machinist and Operative-Engineer

By J. H. Rodgers

Doubtless some of the elementary work in the first few articles of this series may appear more or less superfluous, but it must be remembered that numerous simple rules and formulae appear from time to time in Technical Journals, which are discarded and dubbed impractical by many operators for the simple reason that the elementals are either unknown or have been forgotten. The purpose of this course will have been achieved if the above tendency is even in part combatted.

IN our February issue the introductory details of the arithmetic course were featured, and progress was noted in the instructional work up to and including multiplication of fractions.

Division of Fractions.

Invert the divisor and proceed as in multiplication.

Example:—Divide 9-16 by ⅜. Inverting the divisor and multiplying, we have

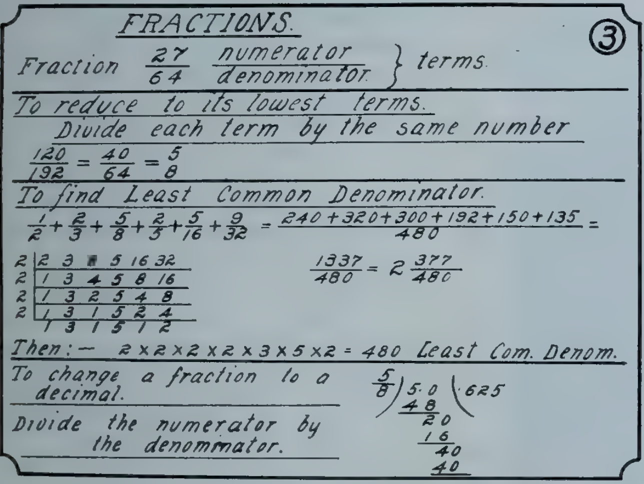
$$\frac{\overset{3}{\cancel{9}}\times\overset{1}{\cancel{8}}}{\underset{2}{\cancel{16}}\;\;\underset{1}{\cancel{3}}}=\frac{3}{2}=1\tfrac{1}{2}$$

Again, $\dfrac{\tfrac{3}{4}\times 5}{\tfrac{15}{64}}=$

$$\frac{\overset{1}{\cancel{3}}\times\overset{1}{\cancel{5}}\times\overset{16}{\cancel{64}}}{\underset{1}{\cancel{4}}\;\;1\;\;\underset{1}{\cancel{15}}}=\frac{16}{1}=16$$

In this case, the product of ¾×5 is to be divided by 15-64.

Examples of this kind may seem to be wandering from the subject of shop work, but as future problems and formulae will require similar solutions, a paragraph here will be of some help when these subjects are met with.



FRACTIONS.

③

Fraction $\frac{27}{64}$ $\frac{\text{numerator}}{\text{denominator}}$ } terms.

To reduce to its lowest terms.

Divide each term by the same number

$\frac{120}{192}=\frac{40}{64}=\frac{5}{8}$

To find Least Common Denominator.

$\frac{1}{2}+\frac{2}{3}+\frac{5}{8}+\frac{2}{5}+\frac{5}{16}+\frac{9}{32}=\frac{240+320+300+192+150+135}{480}=$

2 | 2 3 ▪ 5 16 32
2 | 1 3 4 5 8 16
2 | 1 3 2 5 4 8
2 | 1 3 1 5 2 4
1 3 1 5 1 2

$\frac{1337}{480}=2\frac{377}{480}$

Then:— 2×2×2×2×3×5×2 = 480 Least Com. Denom.

To change a fraction to a decimal.

Divide the numerator by the denominator.

$\frac{5}{8}$) 5·0 (·625

40

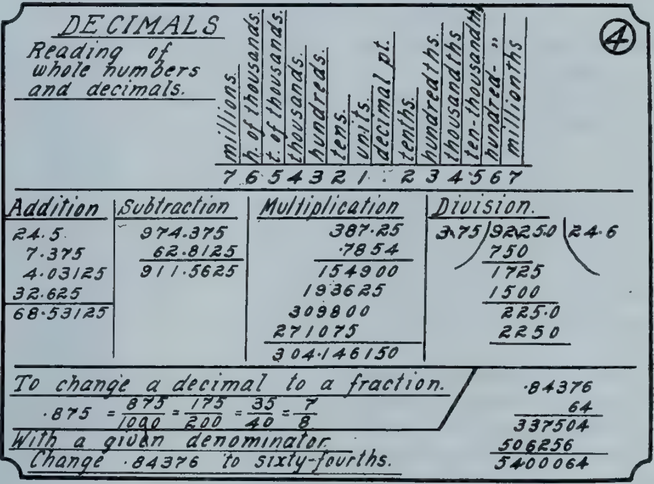
ARITHMETIC CHART 3.

Decimals.

With the exception of the fractions usually met with on the mechanics' steel rule, that is, quarters, eighths, sixteenths, thirty-seconds, etc., the use—and abuse—of common fractions are becoming extinct in the mechanical trades. The use of decimals has become more general, due to the micrometer and other precision tools of accurate measurement. Decimals are tenth fractions; that is, the decimal, or part of a unit, if expressed as a common fraction would have for its denominator ten or a multiple of ten—as 10, 100, 1,000, etc.

In using decimals, the denominator is understood by the number of places represented in the decimal. To express a part of a whole number decimally, a period (.) called the decimal point, is placed directly after the unit figure, and what would be the numerator of a common fraction is placed to the right of the decimal point. The first figure to the right of the decimal point. The first figure to the right of the decimal point represents tenths; the second hundredths; the third thousandths, etc.; similar to a whole number but reading from right to left. Care must be taken when reading or expressing the value of a decimal that the fractional term (ths.) is used.

When ciphers appear in a decimal, their location has much to do with the value of the expression. Thus, expressing ½ as a decimal, we have .5; but .05 would be 5-100 or 1-20. The value of the decimal is taken from the position of the figures in relation to the decimal point, and not from the figures alone. Chart 4.



DECIMALS

④

ARITHMETIC CHART 4.

Addition of Decimals.

Place the numbers to be added so that the decimal points are directly over each other, and add as in whole numbers. The decimal point in the sum will be directly under the others.

Subtraction of Decimals.

Proceed as in ordinary subtraction, keeping one decimal point directly above the other.

Multiplication of Decimals.

Multiply as in whole numbers regardless of the position of the decimal point. In the product, point off from the right as many places as there are decimal places in the multiplicand and multiplier, adding ciphers if necessary.

Division of Decimals.

Place the divisor to the left of the dividend. If the divisor is a decimal, cancel or remove the decimal point, and move the decimal point in the dividend to the right an equal number of places; then divide as in whole numbers. Consider the point in the dividend as a figure, and place it in the quotient when met with in the process of the division.

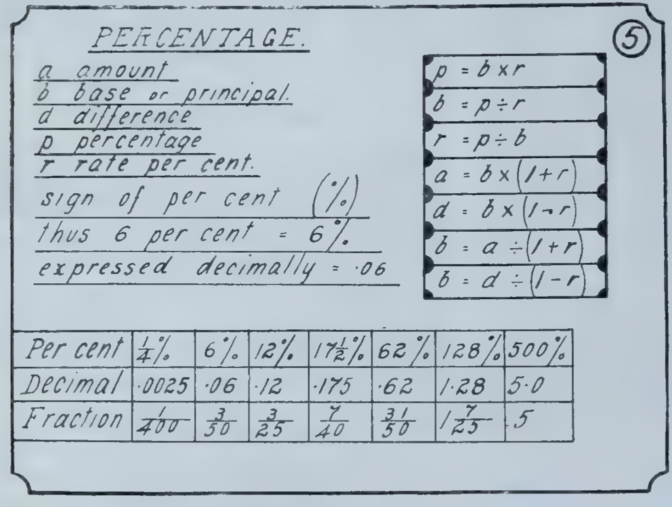
To change a fraction to a decimal annex ciphers to the numerator and divide by the denominator. Point off as many decimal places in the quotient as there are ciphers annexed.

To change a decimal to a fraction. Under the figures of the decimal, place 1 with as many ciphers to its right as there are decimal places in the decimal, and reduce this fraction to its lowest terms.

To change a decimal to a fraction having a given denominator, multiply the decimal by the given denominator. The integral part of the product will be the numerator of the fraction.

Percentage.

Percentage is the process of calculating by hundredths. The sign of percentage is %, and is read per cent.; thus, 7% reads seven per cent. The different elements used in percentage are:—base, rate per cent., percentage, amount and the difference. The base is the number on which the per cent. is computed; the rate is the number of hundredths of the base to be taken; the percentage is the portion of the base indicated by the rate; the amount is the sum of the base and the percentage, and the difference is the remainder obtained by subtracting the percentage from the base:—(see Chart 5).



PERCENTAGE.

a amount
b base or principal.
d difference
p percentage
r rate per cent.
sign of per cent (%)
thus 6 per cent = 6%.

Sq. root of Fraction

$$\sqrt{\frac{25}{64}} = \frac{\sqrt{25}}{\sqrt{64}} = \frac{5}{8}$$

or

Change to a decimal

$$\sqrt{\frac{25}{64}} = \sqrt{{\cdot}390625} = {\cdot}625$$

ARITHMETIC CHART 6.

Example:—The output of a certain factory was 275 cars a year; by the introduction of new machinery, the increase in production was 18%. What was the new output?

Here, the 275 is the base; the rate 18% expressed in hundreths is 18/100 or .18; the percentage of increase is the base × rate, or $275 \times .18 = 49.50$.

The amount or new output would be the base, 275 + the percentage or increase, 49.50; or, by direct formula, the amount=base × (1+rate), or new output $= 275 \times (1+.18) = 275 \times 1.18 = 324.50$.

Involution and Evolution.

This section which is much used and almost indispensable in the solution of many mathematical problems, although apparently quite difficult when first studied dissolves itself, like most others, into an application of the four elementary principles of arithmetic:—addition, subtraction, multiplication and division.

The product obtained by multiplying a number by itself is called a power of that number. This process is called involution. Example, $3 \times 3 = 9$, then 9 is the second power of 3, and the third power of $3 = 3 \times 3 \times 3 = 27$.

To show to what power a number is to be raised, a small figure called an exponent is placed to the right and a little above the number: thus, $4^2 = 4 \times 4 = 16$, and $12^3 = 12 \times 12 \times 12 = 1728$.

The number being raised to the required power is called a root of that power. To find any power of a number, multiply the number by itself as many times as there are units in the exponent.

Evolution is the reverse of involution, being the process of finding the root of a number which is considered as a power.

The square root of a number is that number which, when multiplied by itself, produces the number. Thus, 9 is the square root of 81, since $9 \times 9 = 81$.

The cube root of a number is that number which, when multiplied by itself three times produces the number. Thus, 4 is the cube root of 64, since $4 \times 4 \times 4 = 64$.

The radical sign √ when placed before a number, indicates that some root of the number is to be taken, and, to indicate what root is required, a small figure, called the index, is placed to the left and above the radical sign. Thus,

$\sqrt{16}$ denotes sq. root of 16.
$\sqrt[3]{343}$ denotes cube root of 343.
$\sqrt[4]{27.42}$ denotes fourth root of 27.42.

Square Root.

To extract the square root of a number, see Chart 6.

Example:—To find $\sqrt{121104}$.

Begin at the units place, and separate the number into periods of two figures each. Thus 12, 11, 04.

Find the greatest number whose square is contained in the first or left hand period; write this figure as the first figure in the root, also write it to the left of the given number. Thus,

3 12, 11, 04 3.

Multiply this number at the left by the first figure of the root, and subtract the result from the first period, then annex the second period to the remainder. Thus,

3	12, 11, 04	3
	9	
	——	
	311	

Add the first figure of the root to the number in the first column on the left, and annex a cipher to the result. This is the trial divisor. Divide the dividend by the trial divisor for the second figure in the root and add this figure to the trial divisor to form the complete divisor. Multiply the complete divisor by the second figure of the root, and subtract the result from the dividend. If this result be larger than the dividend, a smaller number must be used for the second figure of the root. Annex the third period to the last remainder for a new dividend. Add the second figure of the root to the complete divisor, and annex a cipher for a new trial divisor. Thus,

3	12, 11, 04	34
3	9	
—	—	
60	311	
4	256	
—	——	
64	5504	
4		
—		
680		

Continue in this manner to the last period.

3	12, 11, 04	348.
3	9	
—	—	
60	311	
4	256	
—	——	
64	5504	
4	5504	
——	——	
680		
8		
——		
688		

Then $\sqrt{121104} = 348$.

ASSOCIATION AND PERSONAL

A Monthly Record of Current Association News and of Individuals
Who Have Been More or Less Prominent in the Power Field.

Athol Davies, the stationary engineer who was badly burned when an explosion of natural gas occurred on Tuesday morning, February 24, and wrecked the boiler-room at the generating plant of the Chatham, Wallaceburg and Lake Erie Railway, Chatham, Ont., died at St. Joseph's Hospital on February 27. John Montague and William Roberts, firemen, who were also injured, are progressing favorably, and will recover.

Hamilton, No. 2, C.A.S.E.—On a recent evening, Hamilton, No. 2, C.A.S.E., accompanied by Executive President S. E. Cosford and Executive Vice-President A. W. Heath, journeyed to Brantford on a fraternal visit to Brantford, No. 4, C.A.S.E. They were met the station and escorted to the lodge room. An open session was held, with the Executive President, S. E. Cosford, in the chair. A very pleasant evening was spent by all, a varied programme of speeches and recitations being the feature. The Executive President urged upon all present to do their best towards increasing the membership of the Order. An invitation was extended to Brantford members to visit Hamilton at an early date, which was accepted. We have had several very good addresses lately by representatives of the Murphy stoker, and the Call Rotary Engine. The blackboard is in use every evening. Electricity forms a very prominent feature in our discussions, and the question box is being used to much advantage.

Chatham, No. 21, C.A.S.E. held an open meeting on Thursday, Feb. 19th, which was well attended, Bro. Joe. H. Stoliker, presiding. The meeting was held for the purpose of encouraging to the lodge room engineers who are not members, and to bring before them the work of the C.A.S.E. The evening was spent as follows: Bro. C. Kelley gave an address covering the development of the C.A.S.E. from its beginning in May, 1887, up to the present time. Bro. Ed. Grandboise read a paper on the use of indicator. Bro. William Condon read a paper on the selection of oils and lubrication. Bro. John Basley gave an address on behalf of the C.A.S.E. while a number of other short addresses were given along the same lines. Bro. Joe H. Stoliker took up some work on the blackboard which was interesting to all. The next open meeting will be held on March 19th. Good metings have been the rule all through the winter, and six applications for membership were received as a result of the above mentioned open meeting.

* * *

NEW C.A.S.E. LODGE AT MONTREAL.

THERE has long been a feeling among the leading stationary engineers of Montreal that there existed a very real need for an association, similar to those in other provinces, by means of which their interests could be looked after. There are already two such associations or societies in Montreal, but both are entirely French in character and sympathies. Hence it was quite clear that in the Dominion's commercial metropolis there was ample room for another society of engineers.

H. L. SACKETT,
President C.A.S.E. Lodge No. 1, Montreal.

This being the case, a number of prominent stationary engineers in the city got together and approached the executive council of the Canadian Association of Stationary Engineers with a request for a charter giving them power to form a Montreal lodge. This request was readily granted, and on February 27, Brother A. Kastella, executive secretary, went from Ottawa to Montreal to open the new lodge, henceforward to be known as Montreal Lodge No. 1, C.A.S.E.

As a start, twenty-five charter members were initiated, their names being as follows:—W. Brown, J. Carmichael, F. Cunnington, W. Fife, J. Forbes, W. Forbes, R. Gallimore, A. Hall, E. Holmes, — Hudson, W. J. Johnston, A. L. Jones, C. H. Lloyd, J. Mitchell, A. S. Parker, H. K. Paton, — Poleman, C. Ralph, H. L. Sackett, A. J. Smith, M. Smith, R. D. Smith, W. Smith, I. J. Tait, and S. Winter.

Brother Kastella also installed the officers previously elected by the lodge. These are:—Past president, C. H. Lloyd; president, H. L. Sackett; vice-president, R. D. Smith; treasurer, J. Mitchell; financial secretary, J. W. Johnston; recording secretary, A. L. Jones; conductor, W. Brown; doorkeeper, J. Carmichael.

The utmost enthusiasm is being shown by the members of the new lodge, and numerous applications for membership are being received. It is expected that fully twenty-five more members will be elected at the next meting.

The objects of the C.A.S.E. are set forth in the preamble to the constitution as follows:—

"This association shall at no time be used for the furtherance of strikes or in any way interfere between its members and their employers in regard to wages. It shall recognize the identity of interests between employer and employees, and shall not countenance any project or enterprise that will interfere with perfect harmony between them. Neither shall it be used for political or religious purposes. Its meetings shall be devoted to the promotion of education, professional and mechanical knowledge."

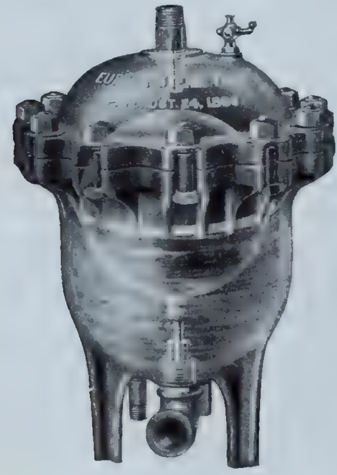
The twenty-five charter members of the new lodge represent some of the most important power plants in Montreal, and all are working hard to gather in other members and make Montreal Lodge No. 1 one of the most successful in the association.

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

THE EUREKA STEAM TRAP.

THE manufacture of the Eureka steam trap has recently been taken over by the Racine Tool and Machine Co., Racine, Wis. As may be seen from the illustration, the trap is simple in construction, and is stated to be positive in action. The valve is controlled by a copper ball float, and the weight of this float, together with the steam pressure, keeps the outlet closed until such time as the buoyancy of the float overcomes both its own weight and the unbalanced pressure on top of the stem. The valve then immediately lifts wide open and the water is discharged; thereupon the float falls and again closes the valve. The valve is thus always wide open or entirely closed as the flow of condensation requires. During the time the trap is discharging, a vortex is created which causes the float to revolve, thereby automatically grinding the valve on its seat at each operation, thus keeping it tight and assisting the water seal to prevent leakage of steam. The valve seat is extended up into the vessel in order to protect it from damage from sediment which may collect in the bottom of the trap.



THE EUREKA STEAM TRAP.

An interesting feature claimed by the makers is that the valve opens and closes instantly. The float does not, as might be expected, rise gradually with the rise of the water; but is so adjusted that as soon as the latter reaches a certain level, and not till then, the valve is suddenly opened. It is claimed that this trap will elevate the water two feet for every pound of steam pressure available. It is made in two styles, one for low pressure service and the other for high pressure. The former is used for pressures from 4 to 50 pounds, while the high pressure type is intended for use from 50 to 175 pounds pressure.

The Foss & Hill Machinery Co., Montreal, are sales agents for this trap.

◆

AUTOMATIC CONDENSATION PUMP AND RECEIVER.

THE automatic condensation pump and receiver here illustrated is, as will be noted, a self-contained unit, therefore, easy of installation. It is only necessary to connect the return line to the tank, run a pipe from the discharge opening of the pump to the boiler and connect the electric wires from the starting switch on top of the bank to the nearest light socket.

AUTOMATIC CONDENSATION PUMP AND RECEIVER.

As the condensation flows from the return line into the tank, it raises a reinforced copper float, which is vented to the atmosphere, so that it will not be affected by the change of temperature in the condensation of water.

This float operates an electric switch that starts the motor and pump. The lowering of the float as the condensation water is pumped from the tank back to the boiler throws the switch out and stops the pump and motor.

The operation being automatic no attention is required aside from an occasional oiling of the pumps and motor. The suction of the pump is extended to the bottom of the tank so that practically all of the condensation water is returned at each operation. The receiving tank is small enough so that the condensation water is returned frequently, and is not cooled to any great extent.

Thomas & Smith, Inc., Chicago, are the makers of this apparatus.

◆

GEORGE WESTINGHOUSE DEAD.

GEORGE WESTINGHOUSE died suddenly on March 12, in New York. He was sixty-eight years of age and was perhaps best known as the inventor of the air brake which bears his name, and which revolutionized railroading. The airbrake which he invented is used thhroughout the civilized world, and in almost every part of the globe there are great plants which he founded.

He founded many manufacturing companies in the United States, Canada and abroad, the latter including plants at Hamilton, Ont., Canada, Manchester and London, England. In the Westinghouse industries some 50,000 persons are employed and the many Companies have a capitalization aggregating $200,000,000.

He was literally a horny-handed son of toil, for his hands were hardened and seared from much contact with tools and metal. Those who knew him best called him "the man who worked." He had to meet financial difficulties more than once after becoming famous as an inventor and manufacturer, but overcame them, and a few years ago his personal fortune was estimated at $50,000,000. His wife, whom he married in 1867, and one son, George Westinghouse, Jun., survive him.

POWER PLANT DEVELOPMENTS

A record of current municipal, manufacturing and general industrial projects, involving steam, gas, oil, electricity, air and water power equipment requirements.

Harriston, Ont.—The large cold storage building of the William Davies Co. has been temporarily closed. It is announced that business will be abandoned at this plant until the arrival of hydro power.

Fort Francis, Ont.—The York Manufacturing Co., York, Pa., recently installed a 4-ton vertical, single-acting, belt-driven enclosed type refrigerating machine, and high pressure side complete, in the Fort Francis Hotel here.

Windsor, Ont.—The Central Ice & Cold Storage Co., Ltd., is asking the city of Windsor for the usual exemptions and not for free water to make ice. They want only such exemptions as are granted to any manufacturing concern. J. H. Green, manager.

Coquitlam, B.C.—The Coquitlam Ice Co., on Dewdney Trunk Road, contemplate extending their plant, and work is to commence immediately on a new ice house on the rear of the establishment. The added building will cost in the neighborhood of $400.

The Babcock & Wilcox Co., Ltd., Toronto, have received an order for four 300 h.p. boilers from the Canadian Kodak Co. for their new factory at Mount Dennis, Ont. They are also supplying a 150 h.p. boiler to the Moose Mountain Mines at Fellwood, Ont.

Ottawa, Ont.—City Engineer Currie has presented a report to the city council for an alternative scheme to the proposed water supply from Thirty-one Mile Lake. The new scheme provides for a mechanical filtration plant and reservoir, the estimated cost being $53,000.

Montreal, Que.—Two new 12-million gallon pumps are to be bought by the city at once, and other improvements are to be made to the pumping system which will cost $144,000. A report to that effect was submitted to the city council on March 4th by the Board of Control. The items in the report are: For a conduit to supply the new pumps, $25,000; two 2-million gallon pumps and boiler building, $85,000; two boilers, $24,000; and a new brick chimney and connections, $10,000; making a total of $144,000.

Windsor, Ont.—The new plant which the Central Ice & Cold Storage Co. will build, will be five stories high, of steel and concrete construction. The building will be 800 x 150 ft., and will have a storage capacity of 500,000 cub. ft. The estimated cost of buildings and equipment will be $150,000.

Northern Electric Co., Ltd.—The recently incorporated Northern Electric Co., Ltd., has taken over the Northern Electric & Mfg. Co. and Imperial Wire & Cable Co. The business previously carried on by the two latter concerns will be conducted by the newly-organized company without change in management.

Ottawa, Ont.—Sealed tenders addressed to the Secretary of the Department of the Interior, Ottawa, Ont., will be received up to noon, 6th April, 1914, for the supply of 13,500 lineal feet of 20-in. diameter lapwelded steel pipe, and 12,000 lineal feet of 6-in. diameter cast iron pipe for the water system at Banff, Alta. Specifications may be had from the Commissioner of Dominion Parks, Ottawa, Ont.

Montreal, Que. — Another step towards the completion of the city's new filtration plant at Point St. Charles, was taken on March 4, with the opening of tenders before the Board of Control, for contract No. 4, comprising pump house and other buildings for the plant. The tenders were referred to the chief engineer for report. The contractors and tenders were: F. J. Jago Co., alternative prices, $155,000 and $159,500; A. G. Loomis & Son, $174,000 and $170,000; Norman Macleod, $193,000, and $199,000.

Humboldt, Sask.—Sealed tenders will be received by the secretary-treasurer until 8 p.m., Wednesday, April 15, for the following works.—(A)—Labor laying water mains and sewers. (B)—Pump house and filter house. (C)—Furnishing material for and erecting water tower. (D)—Furnishing cast iron water pipes. (E)—Furnishing fire hydrants and valves. (F)—Furnishing and installing pressure filters. (G)—Furnishing and installing pumping machinery. (N)—Furnishing wood stave pipe. (O)—Laying wood stave pipe. (P)—Constructing ejector station. (S)—Furnishing sewer pipes. (X)—Constructing sewage disposal works. Plans and specifications may be seen at the office of the engineers, Toronto and Winnipeg, and at the town hall, Humboldt, on and after March 16th. Chipman & Power, engineers, Toronto.

Medicine Hat, Alta.—President Pearson of the Medicine Hat Pure Ice Co., and Mr. Davidson of the same concern, are completing arrangements with the city for a site for their ice plant. It is understood that the site has been secured and without doubt an agreement will be entered into at once. The plant will be one of the largest of its kind, and the firm are contemplating the building of a large skating rink and curling rink in addition to the ice making plant. It is their intention to have the plant completed in time for the summer ice trade.

◆

S. E. Cosford in Accident.—C.A.S.E. Executive President, S. E. Cosford met with an almost fatal injury through falling some 25 feet, while engaged repairing a motor. Contact with a cross bar in his fall, broke all of his ribs on one side, two of them piercing his lungs. His condition was more or less critical for a week, but latest advices state that he is progressing favorably towards recovery.

◆

Boiler Inspection Query.—C. M. McCabe, Totenham, Ont., wishes to know if the Ontario Government laws require all steam boilers, irrespective of size and pressure, to be inspected once a year, whether they have been actually in service or not during the period. The statutes of Alberta and Saskatchewan, he states, make the above inspection necessary.

KEEP YOUR EYE ON THE COAL PILE

If your coal bills are gradually increasing without a corresponding increase of power, there is a reason for it, and it is a safe bet that the increase is caused by scale in your boilers. And if you have scale, the logical thing for you to do is to order a LIBERTY TUBE CLEANER and stop the useless waste.

A LIBERTY CLEANER will pay for itself many times over, and there is no other investment you can make that will pay as large a dividend for the amount invested. Think it over.

We will send you a Liberty Cleaner on trial. If it fails to do your work *better* than any other make of Cleaner, you don't have to keep it.

"TWINS" EXCITE ADMIRATION

Because They Earn It

Think of a TWIN when you hear the word STRAINER

The installation of a Twin Strainer on your water supply line eliminates troubles, worry, waste of time and expense—because

It has two straining baskets—that may be cleaned alternately, thus permitting continuous operation.

It has but two valves—they are of the gate type and are always tight.

It gives a direct flow with minimum friction loss, insuring easy operation with no waste of energy.

In fact, a Twin Strainer is an insurance policy in active service.

Designed to protect and built to last.

Write for our bulletin.

Catalogues

Steam Pumps are dealt with in Catalogue No. 9 recently issued by the Smart-Turner Machine Co., Ltd., Hamilton, Ont. Several types are illustrated and a brief description given of each.

The DeKalb Ammonia Compressor is the subject of a catalogue sent to us by the Creamery Package Manufacturing Co., Chicago. The principal features embodied in the design of this compressor are illustrated and described in a comprehensive manner.

Westinghouse Portable Meters are dealt with at length in a new circular, 1,104, which the Canadian Westinghouse Co., Ltd., Hamilton, have recently issued. Several types are illustrated and described for both a.c. and d.c. current. Copies will be gladly sent to interested readers.

''Lagonda Cut-off Valves'' is the title of an attractive catalogue which has been issued by the Lagonda Mfg. Co., Springfield, O. The valves and other specialties manufactured by the company are illustrated and described fully, the illustrations including views of several installations. Copies of this catalogue may be had by writing.

The Canadian General Electric Co., Ltd., Toronto, are distributing No. A4185, which deals with single-phase induction motors, type K.S. A full description is given of these motors, and the illustrations show the details of construction. A diagram with table is included giving the principal dimensions and weight for each size.

Motor-Generator Sets, small types, M.C. and M.C.C., are dealt with in Bulletin No. A4190, recently received from the Canadian General Electric Co., Toronto. Illustrations are given of all the various parts of these machines, and the reading matter describes them in a full and comprehensive manner. The principal dimensions of each size are given on the last two pages of the bulletin.

Direct Current Generators, small belted type, are the subject of Bulletin A4188 issued by the Canadian General Electric Co., Ltd., Toronto. A complete description covering the constructional features of this type of generator is given, together with illustrations of the various parts of the machine. The bulletin concludes with a diagram and table giving the principal dimensions of each size.

The Vilter Mfg. Co., Milwaukee, Wis., have sent us a copy of bulletin No. 22A, entitled ''Chemistry of Raw Water Can Ice,'' written by John C. Sparks, B. Sc. This bulletin deals with the manufacture of ice, principally from a chemical standpoint, and contains some very interesting data on the subject. The bulletin is a reprint from a paper read before the American Society of Refrigerating Engineers, New York.

The Morse Chain Co., Ithaca, N.Y., has issued a pamphlet, No. 12, entitled the ''Morse Long-Service Chain Drives.'' The pamphlet consists of a number of short descriptions of typical ''Morse'' silent chain drives showing their durability and efficiency for long periods of time. Each installation is illustrated, and a summary is given of all the drives. The pamphlet concludes with particulars regarding the design and operation of the ''Morse'' chain.

The Canadian Westinghouse Co., Ltd., Hamilton, Ont., are distributing a circular No. 1156, dealing with types ''S'' and ''R'' direct-current generators. The description of the generators is equivalent to a specification, as each part is dealt with in detail and illustrated. Other illustrations cover steam engine-driven and motor-generator sets. One section of the circular is devoted to field rheostats, which are also illustrated and described in detail.

Hydraulic Valves and Fittings are the subjects dealt with in catalogue No. 43, issued by the Hydraulic Press Mfg. Co., Mount Gilead, O. Illustrations are given of an extensive line of hydraulic appliances including operating valves of several types, safety or relief valves, accumulator controls, speed governors, etc. The reading matter is very descriptive and includes several tables on dimensions and areas of hydraulic pipes and other useful information.

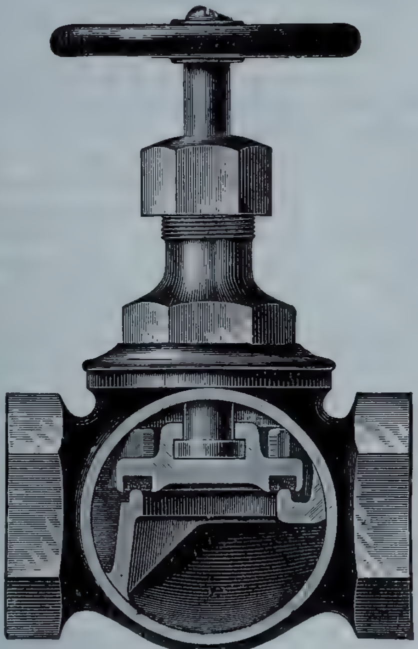
The Canadian General Electric Co., Ltd., Toronto, have issued Bulletin No. A-4064 describing their mill type motors. The constructional features of these motors are illustrated and described at length, each part being treated separately. These motors are specially adapted for working in steel plants and similar service, and are made in various forms, according to the work required of them. The bulletin contains diagrams and tables giving the principal dimensions for each type.

Power Transmitting Machinery is the title of Catalogue No. 35 which we have received from the Canadian Bond Hanger and Coupling Co., Alexandria, Ont. This is a new catalogue and contains particulars of a full line of transmission machinery made by the company. Each type of equipment is illustrated and tables are included giving the principal dimensions, price, and code word of each size. One of the features of the catalogue is the ''Grundy'' flexible insulated coupling, designed for connecting motors to pumps, fans, etc. The catalogue contains an index and telegraph code. Copies may be obtained from the manufacturers or from the Dominion Machinery Co., Toronto, their the Canadian office, 14 Alexander street, Toronto.

The Terry Steam Turbine Co., Hartford, Conn., have sent us a copy of Bulletin No. 17, dealing with the ''Terry'' return-flow steam turbine. The design of this type of condensing turbine is a combination of a multi-velocity stage element for the high pressure end, with a series of multi-pressure stage elements in the low pressure end. The principal features embodied in the design of this turbine are described at length, and the claims for the return-flow principle are dealt with in a comprehensive manner. The illustrations show exterior and interior views of the turbine, while a condensed specification covers the principal constructional features. Copies of this bulletin may be had by writing the company.

Bulletin No. 57 ''The Phenix Sight Flow Indicator,'' recently issued by the Richardson-Phenix Co., of Milwaukee, Wisconsin, illustrates and describes how this unique little device can be inserted in any pipe line carrying a liquid, such as water lines of water cooled transformers and the supply pipes of water jackets of gas engines and air compressors, and how it shows at glance or indicates electrically by lighting a lamp or ringing a bell when the flow of liquid is interrupted. Several recent improvements in the Sight Flow Indicator are also described, showing how it is now possible to adjust the indicator so that it will give an alarm before the liquid stops flowing entirely, that is, when it drops to some predetermined minimum. This improvement has made it especially suitable for use on water-cooled transformers. Copies of the bulletin may be had by addressing the company as above.

Data Book on Silent Chain Drives.—The Link-Belt Company, Chicago, Ill., have published an engineering data book which is designed to enable users of power to select the correct silent chain drives for their work and determine exact costs from list prices shown in the book. eBsides giving much information on silent chain driving in simple and compact form, Data Book No. 125 describes many uses of silent chain for the efficient transmission of power, and gives specific reasons and illustrations showing application in a large variety of uses. Link-belt silent chain consists of a series of links connected by joints, which consist of segmental case-hardened bushings and case-hardened steel



Your Valves play a most important part in your Power Plant Equipment.

FAIRBANKS VALVES

should be used on all your high-pressure lines.

Tested under the most severe conditions, their great durability and strength enable them to give the greatest service.

High-class workmanship, and improved design, by Valve Experts, render them absolutely dependable at all times.

The Fairbanks Renewable Disc

the principal feature of Fairbanks Valves, owing to its composition of long-fibred Asbestos and rubber, with a special binding process, is long lived, unbreakable, tough, yet sufficiently soft to cushion perfectly with the valve seat. The RAISED ROUND SEAT is practically self-cleaning, its shape preventing the lodging of foreign substances which might injure or destroy the seat.

FAIRBANKS DISCS are easily renewed; simply remove the valve bonnet and slip a new disc upon the end of the spindle.

Fairbanks Valves are fully guaranteed, and regular weight valves are tested to 300 lbs. hydrostatic pressure.

Specify these valves for all your high-pressure lines, and be certain of getting the highest valve efficiency.

We can supply the demand for packings for any purpose. All Fairbanks Valves are packed with PALMETTO twist packing. You will save a lot of trouble with your valves if you do likewise. You know then that they will remain tight.

pins. The chain, it is claimed, is as flexible as a leather belt, as positive as a gear, and its rated efficiency 98.2 per cent. on actual test. Over 200,000 installations, we understand, were drawn upon for the information contained in this data book. Copties of the book, which consists of 112 pages, bound in flexible red cover, can be obtained by addressing the Link-Belt Company, 39th Street and Stewart Avenue, Chicago.

The Canadian General Electric Co., Toronto, have issued bulletin No. A4185 dealing with single-phase induction motors, type KS. A full description is given of this motor with detailed illustrations. One page shows a diagram of the motor with a table giving the principal dimensions and weights for the different sizes.

The Johnson Temperature Regulating Co., of Canada, Toronto, have issued two pamphlets dealing with the "Johnson" system of temperature and humidity regulation. The system is described in detail, as are also the thermostats and other equipment installed in the system for various services. The illustrations include diagrams of systems, views, of thermostats, diaphragm and reducing valves, also of numerous buildings equipped with the "Johnson" system.

Boylston Steam Specialties are dealt with fully in Catalogue No. 10 which we have received from the Boylston Specialty Co., Chicago. The apparatus listed covers a full line of fittings for steam heating systems, such as valves, regulators, traps, etc. Each type of fitting is illustrated and described, while several pages are devoted to useful information covering heating systems and properties of steam. An interesting piping lay-out is included showing the location in the system of the various fittings listed.

Peebles Alternating Current Motors is the title of a pamphlet No. 22A recently issued by Bruce Peebles & Co., Ltd., Edinburgh, Scotland. The pamphlet is divided into two parts, one dealing with open type machines and the other with a self-contained type, both types being polyphase induction motors in large sizes. A general specification is included, while illustrations give a general idea of the design. In addition, there are a number of tables giving the principal dimensions, weights, H.P. and other data covering the various sizes. The pamphlet concludes with a list of customers and a list of foreign and colonial agents.

F. Ross Newman, resident manager in Toronto of the Canadian Fairbanks-Morse Co., Ltd., has returned from Europe, having been away about six weeks.

Book Reviews

The Canadian Peat Society, Ottawa, have published their quarterly journal devoted to the peat industry and its advancement. The journal contains articles on peat moss, Canada's peat industry, the "Moore" gas producer, etc., also editorial comments on various matters relating to the peat industry, by-products obtained, and possibilities for development. The journal contains a number of illustrations of operations at Alfred, Ont.

List of Boiler Manufacturers.—The Supplymens' Association of the American Boiler Manufacturers' Asociation announce the completion of their list of boiler, tank and stack manufacturers of the United States and Canada, which is compiled in neat booklet form and contains names and addresses of something over 900 manufacturers. These books are offered to interested parties, such as tool and material manufacturers for the sum of three dollars ($3.00) per copy. Address, F. B. Slocum, Secy., C|o. The Continental Iron Works, West and Calyer Sts., Brooklyn, N.Y.

How to Build Up Furnace Efficiency, by Jos. W. Hays, combustion engineer, 126 pages, several illustrations and diagrams. Published by Jos. W. Hays, Chicago, Ill. Price, $1.00 post free. This is the seventh edition, revised and enlarged, of a handy little publication devoted to the subject of fuel combustion. It has been written with the idea of showing engineers and superintendents how a reduction in coal consumption can be accomplished in a practical manner. The subject is treated in a scientific, yet at the same time, in a thoroughly practical manner. The reader's attention is drawn to the waste of fuel, common in many power plants, a table on page 7 giving the heat losses in detail, from the coal, at the mine, to the heat delivered at the machine. The book is divided into practically five sections, which may be classified as follows: Why fuel is wasted; how fuel is wasted; how to spot fuel wastes; how to stop fuel wastes, and how to keep fuel wastes stopped. The subject in each section is dealt with fully and is accompanied by diagrams, views of apparatus, etc.

Condensed Catalogues of Mechanical Equipment have been published by the American Society of Mechanical Engineers, New York. This is the third annual (1913) volume of what is really a desk reference book of mechanical equipment, containing, as it does, 330 pages of condensed catalogue material. The purpose of this volume is to present in a concise form such facts concerning distinctive features, sizes, capacities, and special adaptations of mechanical equipment as are likely to be required for purposes of preliminary reference by engineers, superintendents, managers, etc. Practically all the important firms in the United States making power plant, machine shop and contractors' equipment, are represented in this book, one or more pages being devoted to each company for illustrating their principal products. The data is taken from the various manufacturers' catalogues and is arranged in catalogue form in a condensed manner. The arrangement makes it possible to use the volume as a reference book, as further information can be obtained from the usual sources. Both page and classified indexes are included in this book, which is bound in a substantial manner. The illustrations are good and the reading matter well arranged.

Elementary Manual of the Steam Engine, by Ernest V. Lallier, 250 pages, 7¾ x 5 in. 102 illustrations and diagrams. Published by the D. Van Nostrand Company, New York. Price, $2.00 net. This book, as the title indicates, is an elementary manual and is written primarily for students of steam engineering and young men engaged in the actual operation of steam plants. The author's main endeavor has been to present in a thoroughly practical and elementary manner, the use of steam, and give data relative to the operation of steam plants. The first chapter begins with a description of the reciprocating engine and its various parts and its method of operation. A chapter is devoted to the governor feature. Engine horse power is treated briefly in one chapter, but is discussed further in a chapter on the indicator. The chapters on steam and its exhaustive working are comprehensive and will be readily understood. A separate chapter has, however, been devoted to heat, this subject being treated independently of steam. Boilers, water and fire tube, are described at length, 42 pages being devoted to this section, which includes also a chapter on boiler calculations. Steam turbines are described briefly in the chapter on rotary engines, while 28 pages are devoted to a description of internal combustion engines. Other subjects dealt with include Corliss engines, pumps, pipes and fittings, while the last chapter is devoted to lubrication. At the end of each chapter is a series of questions which help to bring out the chief points of the subject under discussion and are a useful adjunct to a work of this description. The book is printed in clear type and bound in serviceable covers. It should be very helpful to those who are beginning to study the many problems associated with steam engine operation, as it is written in a manner so as to be readily understood.

Boiler Preservative

acts on the iron—not on the water. It is a boiler treatment in a class by itself.

Water treatments are only partially successful, because the scale-forming sediment in water changes with seasons, climates and localities.

"MAGIC" removes scale and oil first, and then prevents scale forming. It stops pitting, corrosion and minor leaks.

"MAGIC" saves the boiler and much labor.

A trial will convince you—write us.

PLEASE ADDRESS ALL COMMUNICATIONS TO THE COMPANY NOT TO INDIVIDUALS

Nova Scotia Steel & Coal Co.
LIMITED

New Glasgow, N.S. February 9, 1914.

The Hare Engineering Company, Limited,
Toronto, Ont.

Gentlemen:

Replying to your letter of the 4th inst, we have to say that one of your FULTON Stokers was installed under one of our 316 H.P. Stirling boilers, where it was worked both shifts continuously for about three months.

In view of the records taken and the condition of the stoker and the boiler at the end of the test period, we felt warranted and decided to equip the remaining eight (8) Stirling boilers at our New Glasgow plant with your type of stoker. This decision was reached after comparative tests of the FULTON as against various types of Chain Grates.

The FULTON has a marked superiority when burning an inferior grade of fuel, due to the facility with which ash can be removed, and the advantages accruing from the continuously clean and bright fire.

As to efficiency in overload capacity, may say that during the special test carried out for the purpose of demonstrating the overload capacity in which the stoker was supplied with Culm coal giving between 12,000 and 13,000 B.t.u., we were able to secure 100% overload on the boiler referred to. From our experience when burning this grade of coal on the FULTON stoker under ordinary daily conditions we are satisfied that the percentage of overload will approximate 50%.

While your FULTON stoker has not been running long enough to fully demonstrate the measure of repairs over a long period, yet our experience has been such as to indicate that the repairs will be light; and apart from the fact that it will be necessary at times to lay the boiler off for washing out and cleaning of tubes, the boiler might be run continuously so far as the stoker installation is concerned.

We shall be pleased to supply any further information and you are at liberty to make use of this letter with prospective customers, and the stoker may be inspected by you or your friends at any reasonable time.

Yours truly,

Nova Scotia Steel & Coal Co. Limited

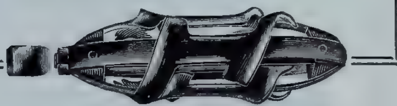
Toronto, Can.

Model B, $1.00 per inch.



DIXON'S

Graphite Greases

No grease or oil can be depended upon to stay in a bearing. But make the best mineral grease a vehicle for the distribution of pure flake lubricating graphite, and you have the most efficient lubricant in the world. That is what Dixon's Graphite Greases are — and there's a Dixon's Graphite Grease for every anti-friction purpose. The graphite remains to lubricate the bearing even after the grease is gone. Send for Grease Booklet No. 222.

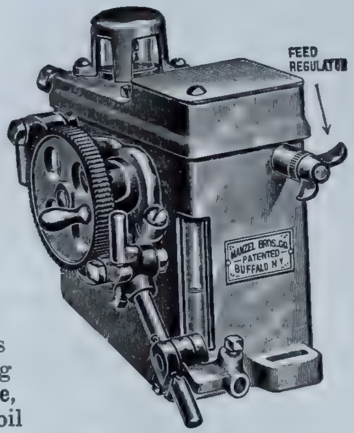
For speed tests on engines, generators, turbines, or any machinery, nothing is so reliable and accurate as the **Starrett Speed Indicator**

It indicates the highest speed without heating. Small and convenient. Three styles—$1.00, $1.50, and $3.00.

Send for free catalog No. 20 CD and see what style you need.

The L. S. Starrett Co.
World's Greatest Toolmakers
Athol, Mass.

Don't lubricate the floor.



Saturating everything with oil, for ten feet around your engine, won't help things any. Lubricating the floor won't reduce cylinder friction. Besides which, it is very expensive—good oil costs money.

The **Manzel Sight Feed Oil Pump**, because it delivers a definite and unvarying amount of oil **per stroke**, because it puts that oil where it is required, because it doesn't lubricate the floor as well as the engine—reduces cylinder lubrication to a minimum, and cuts your oil bills anything from 30% to 60%.

And the proof is our 30 days' free trial offer.

Test it to-day—at our expense.

It's hard work – Scurfing

Nasty, hot, uncomfortable work, too. But it's your duty, and, like a good engineer, you put duty ahead of personal likes and dislikes.

Just a moment, though! You want to try **Walker's Electric Boiler Compound** in your feed water. It will cut out all the scale, keep your boilers clean as can be, and stop your having to do any scurfing whatever.

And mind you, it won't injure them in the slightest nor interfere with the pumps in any way.

Let us send you a barrel—to try out. If it's not up to specifications return it at our expense—there'll be no charge to you whatever.

That's a pretty fair offer, isn't it?

Then write now, we have a catalog covering all our power house supplies waiting for you.

PRACTICAL BOOKS FOR PRACTICAL MEN

These books were written especially for practical self-instruction, by experts whose experience and standing make them authorities.

They are so clear that the beginner can understand them; so thorough that the trained worker can learn from them; so practical that they will give any man a working knowledge of the subjects that they treat, and save him both time and money.

They not only cover the fundamental principles of mechanical science, engineering practice, and business usage, but also present the latest developments and the accepted practice of the most successful men, in those lines.

They give men a practical knowledge of practical things, which enables them to think more accurately and to work more efficiently; and they compose the most helpful, reliable, and comprehensive series of home study books ever put upon the market.

The Detroit "500" will not syphon

The Detroit "500" Air Compressor Lubricator gives constant lubrication under every condition of service. The rate of feed never varies when changing from pressure to unloading or when returning from unloading to pressure.

The Detroit "500" cannot be robbed of oil and cannot be affected by changing conditions in the cylinder.

This lubricator can be started and stopped without changing the feed adjustment, preventing both loss of time and oil when starting up.

The bullseye gauge and sight feed glasses are kept tight and won't break. This lubricator will withstand the roughest service.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS

TO THE STATIONARY ENGINEER WHO IS NOT A MEMBER OF THE C. A. S. E.

Have you ever seriously considered the necessity of mingling freely with your fellow-men whose life's occupation is the same as your own? If you have not, I would like to place before you the advantages which accrue to all thus associated.

We preach the doctrine of elevation of the Engineers through the medium of education.

By joining one of the subordinate associations of the C.A.S.E. you can gain knowledge of the character which is deemed so essential by successful practitioners of all the useful professions.

In all fairness I would ask you if an organization devoted to the calling at which you earn your daily bread is not entitled to special consideration from you?

WHY USE OIL

When GREASE Gives More Uniform Lubrication, Is Better and Much Cheaper?

This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

'Ware the "March Lion!"

FEED WATER IMPURITIES slip into your boilers unobserved like the proverbial lamb—and become a "roaring lion" of destruction.

The Problem with every steam power plant operator is, how **best** to get rid of these fuel-wasting, power-killing, boiler-destroying elements.

Now you wouldn't go *lion hunting* with a mouse trap, a fish net, a shot gun or a brass cannon—these weapons are all right for their purpose, but *no good for lions!*

R You would carefully select your weapons for the particular kind of game you sought to kill—fighting materials of proven efficiency!

R Now, how can you select weapons of proven efficiency to fight feed-water elements that cause Scale, Corrosion, Pitting, Foaming, Priming, etc., in your boilers until you have determined exactly what those elements are?

R Feed waters show a surprisingly wide range of variation in analysis—boiler plant conditions also vary—no two problems are ever exactly alike. There are many different kinds of scale, and many different chemical constituents of water that will cause corrosion and other boiler troubles. And there's a right re-agent for every one of these destructive elements and a right way to use it under every condition.

R To attempt to treat all feed waters with one formula is a good deal like mixing fish bait, rat poison, bird shot and cordite powder into one ammunition and then going out with the vague hope of "bagging something"!

R Nor can any substance by "mechanical action" hope to cope efficiently with distinctly chemical conditions. DEARBORN WATER TREATMENT is the logical way, the proven way, the one unfailingly dependable way out of your feed water troubles—

R Because—by expert chemical analysis and report, at our own invitation and expense, it first determines the exact conditions, with scientific accuracy, and then prescribes the right re-agents, carefully compounded in exactly right proportions, to meet those conditions.

R This is our chosen field of service—we were the pioneers in it and are masters of it; our laboratory and manufacturing equipment stands unique in extent and modern efficiency. Thousands of power plant operators in every civilized nation, attest the Integrity, Efficiency and Economy of Dearborn Water Treatment. Just why do you hesitate?

Send a one-gallon Sample, in clean container, of the water in exact condition as it enters the boiler—(after passing the heater if one is in use)—state source of supply, well, lake or river, and whether water has been treated by any method.

DART

Union Pipe Coupling

REDUCES EXPENSE

Absolutely Trouble-Proof

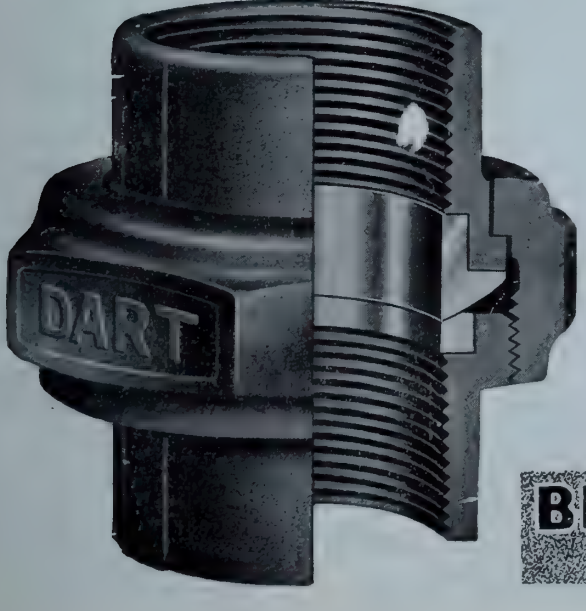
When pipes are connected with a Dart Union there is no possible chance of a leak, and as both faces are of bronze there is no corrosion at the joint.

After a Dart Union has served years in one place you can disconnect it and put it on some other job. It can be used over and over again, and still retain its original efficiency.

Vibration, contraction or expansion do not affect it in the slightest degree.

Every Dart Union bears the trade-mark as shown on illustration. This is our **guarantee**: we replace two for one any Dart found defective.

Sold by Jobbers from Coast to Coast.



Dart Union Co., Limited

Self-Lubricating

SAFETY PLASTIC
METALLIC PACKING

Practically Frictionless

FOR STEAM, WATER, AIR, GAS, ETC.
LASTS FOR YEARS AND NEVER WEARS THE PISTON ROD.

Guaranteed to stand steam temperature up to 550 degrees Fahr.
Guaranteed to stand hydraulic pressure to 5,000 pounds per square inch.
Packing furnished in bulk and in thin Cotton Tubes, sizes 3-16 to 1½ inch, 36 inches long, or in special lengths to fit your stuffing boxes.
Empty Cotton Tubing in assorted sizes FREE OF CHARGE with orders for the packing in bulk form.
The tubes are easily filled and they save you the expense of carrying a large stock of packings in different sizes.

Send for FREE SAMPLE and particulars.

In Cans
6, 12, 25 and 50 lbs.

Manufactured only by
STEEL MILL PACKING CO., WINDSOR, ONT.

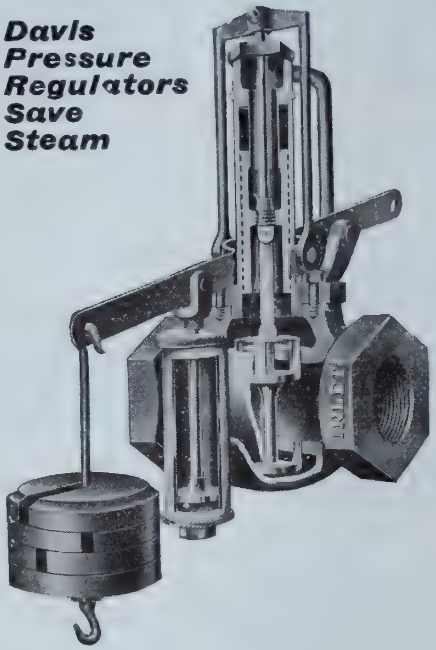
Put this valve on your steam line and forget about the pressure.

Davis Pressure Regulators Save Steam



Besides the economy of the thing, there is much satisfaction in being able to get any pressure you want in your plant regardless of the boiler pressure.

No matter what the operating conditions may be, if the result you want to get is a lower pressure for a given purpose, you have at your command the

DAVIS Pressure Regulator

This automatic valve may be set for any delivery. Fluctuations in the high pressure do not affect its action, and it is good for years of service because it is very simple in construction.

All Davis Pressure Regulators are sold on approval at our risk. They must satisfy you fully or there is no sale. Let us have your inquiries.

Made in all sizes from ½ to 14-inch, with either screwed or flanged ends.

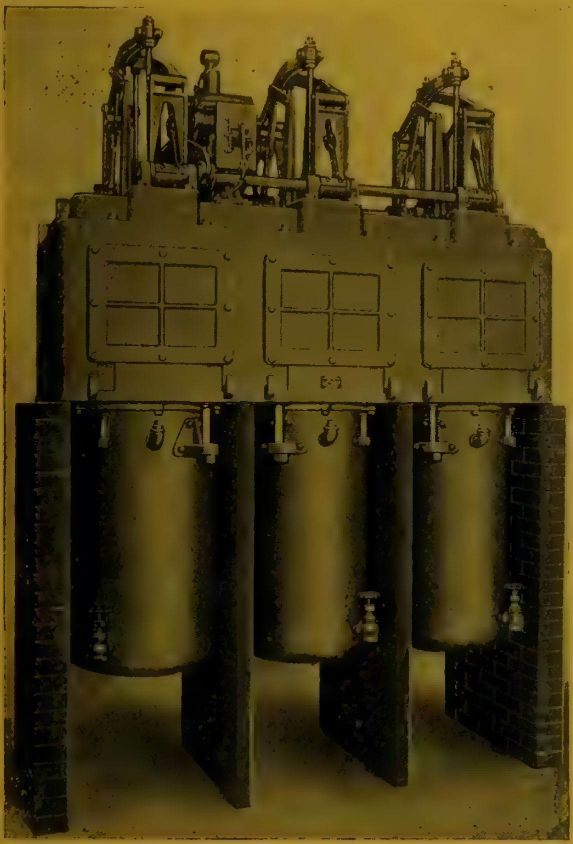
Westinghouse

Reactance-Type Circuit Breakers

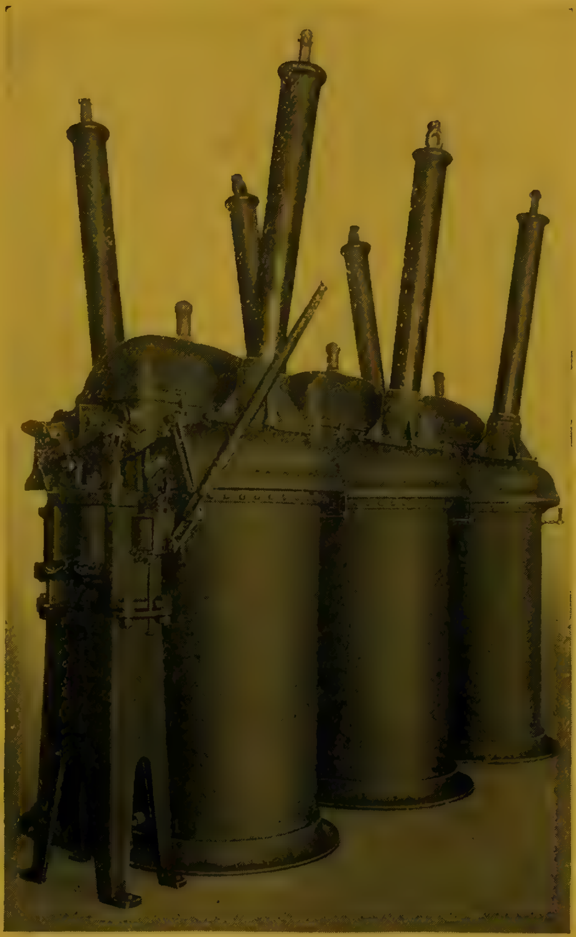
THESE breakers have two sets of contacts giving four breaks per pole, with self-contained reactance in shunt to one set of contacts.

One set of contacts opens first, thereby cutting the reactance into the circuit. The second set of contacts then act immediately, completely opening the circuit. The proper sequence of operation is insured by a positive mechanical interconnection.

This action first limits the flow of current under short-circuit conditions, and absorbs the inertia and stored energy of the system, making the work of the final pair of breaks relatively light.



Westinghouse Reactance-Type Circuit Breaker, Solenoid Operated, showing cell structure with doors removed. Capacities up to 1,200 amperes and 25,000 volts.



Westinghouse Reactance-Type Circuit Breaker Solenoid Operated. For floor mounting, showing breaker open with hand-closing lever in position. Capacities 600 amperes and 110,000 volts. Can be furnished for outdoor mounting.

This scheme of operation limits the work to be performed by the circuit-breaker mechanism, and makes possible a construction of practically unlimited circuit-breaking ability.

Reactance-Type Circuit Breakers are primarily intended for use as feeders, or automatic bus-tie breakers directly on the busses, which in turn are fed directly from a battery of large capacity generators or transformers.

The Morrison Improved J. M. T. Injector

The J. M. T. Injector works under a greater range of pressures than any other injector on the market, operating perfectly on steam pressures from 20 to 220 lbs. gauge. It delivers hot water to boiler at 160° to 212° Fah., according to temperature of feed water and steam pressure. 200° to 212° can always be delivered at nearly all pressures over 50 lbs. by throttling suction valve and delivering the minimum capacity.

The J. M. T. Improved is the acme of simplicity. Any one can take it apart for cleaning with no other tool than an ordinary wrench. All high-pressure injectors are fitted with our improved drain valve, which enables the machine to be drained when necessary to prevent freezing. This valve is also of great assistance in starting on low pressures, and also furnishes a means of obtaining a supply of hot water.

Morrison Brass Valves

We manufacture a complete line of brass valves and cocks for every purpose. The design of these valves represents an experience extending over thirty years. The metal is selected in each case for the purpose for which the valve is intended. The foundry and machine work are all that careful factory methods can accomplish. Each valve is finished and fully tested under pressure before leaving our factory.

There is
A DIFFERENCE

There is a vast difference between steam specialties that LOOK good and STEAM SPECIALTIES that ARE good. The difference is that between a plant always giving trouble—with the engineer working all day Sunday repacking valves, adjusting traps and lubricators, and so on, only to have it all to do over again a week later—and the plant that runs itself, almost, year in and year out.

For more than thirty years we have been making STEAM SPECIALTIES THAT ARE GOOD, and in each of those years studying to make better products than we made the year before. We do not claim perfection, even yet, BUT, we do give you an unconditional guarantee with every article we make.

The J.M.T. trade-mark on a power plant accessory means that that article will do everything that we said it would do and will do it continuously without undue attention. It is an assurance that costs you nothing. It is one of the benefits YOU derive from OUR experience.

We have a complete line of Power Plant Accessories and Brass Fittings for every purpose. Ask us for a catalogue of the line in which you are interested.

STEEL PLATE WORK—

The various kinds of Steel Plate Work used in the modern power plant are turned out by our boiler shop. We build tanks, bins, steel chutes and troughing, smoke breechings, stacks, etc., in all sizes, built to order to suit individual requirements.

By keeping a separate department constantly busy on this work, we have acquired invaluable experience in handling these special jobs to keep down manufacturing costs.

That's why we are able to turn out special built-to-order plate work at a price that is not special.

Send us your sketches for this work. Our prices will suit you.

BRANTFORD, CANADA

Winnipeg, Man. **Vancouver, B.C.**

THE BALLAD OF THE B.T.U.

Said the B. T. U. to the Old Boiler Flue,
  As he quivered and shed a tear,
"I am cussed and maligned, tho the fault is not mine,
  For my failure to make good here.

"I simply can't keep those units all hot,
  When they're half full of condensation.
When traps work as they should, it's a cinch to make good,
  But I'm tired of this situation.

"It's no wonder they're cold, for, as I am told
  By the contractors, estimators,
Most any old trap that would fit on the tap
  Was screwed into these radiators."

"Have cheer," said the Flue to the peeved B. T. U.,
  "Your troubles will soon end, perhaps,
For I heard the Boss say to the fitters to-day,
  He was going to put on new traps."

And the very next morning, without any warning,
  The fitters came on in a mob,
And with wrenches and taps and good Dunham Traps,
  They replaced every trap on the job.

Said the B.T.U. to the Old Boiler Flue,
  And he chuckled in cheerful mood,
"These new traps are fine; it's the Dunham for mine,
  I think I'll stay now and make good."

LISTEN:

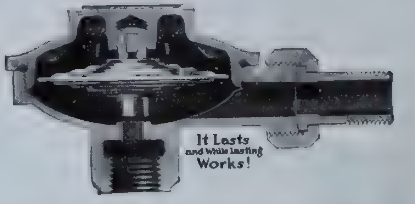
DO your B. T. U.'s give you satisfaction and full value?

IF NOT, have you ever taken the trouble to investigate and find out WHY NOT?

IS IT leaky, faulty radiator traps, or maybe the need of good traps?

The B. T. U. Ballad may be chanted to a successful ending of your boiler troubles and cold Radiators if you ask us about the

Dunham Radiator Trap



Performs the functions of a Radiator Steam Trap perfectly and continuously. Eliminates water and air without loss of steam.

Let us get together on your particular proposition of heating. We can do each other good.

Write for our new Bulletin Catalog and particulars TO-DAY.

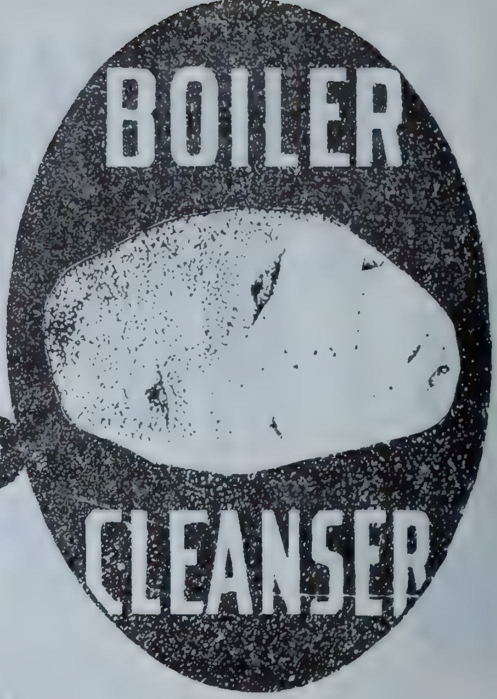
Potato Scale



The destructive and money-wasting scale hasn't a "ghost" of a show where this boiler compound is used.

Its services ensure clean boilers, a minimum consumption of fuel, and freedom from pitting, corrosion, foaming and other troubles due to the impurities in the feed water.

There is nothing in its composition that can cause the slightest injury to metal.

We treat each case individually and **guarantee** satisfactory results.

Let us furnish you with references and full particulars. **Don't miss this opportunity to profit by the experience of other engineers.**

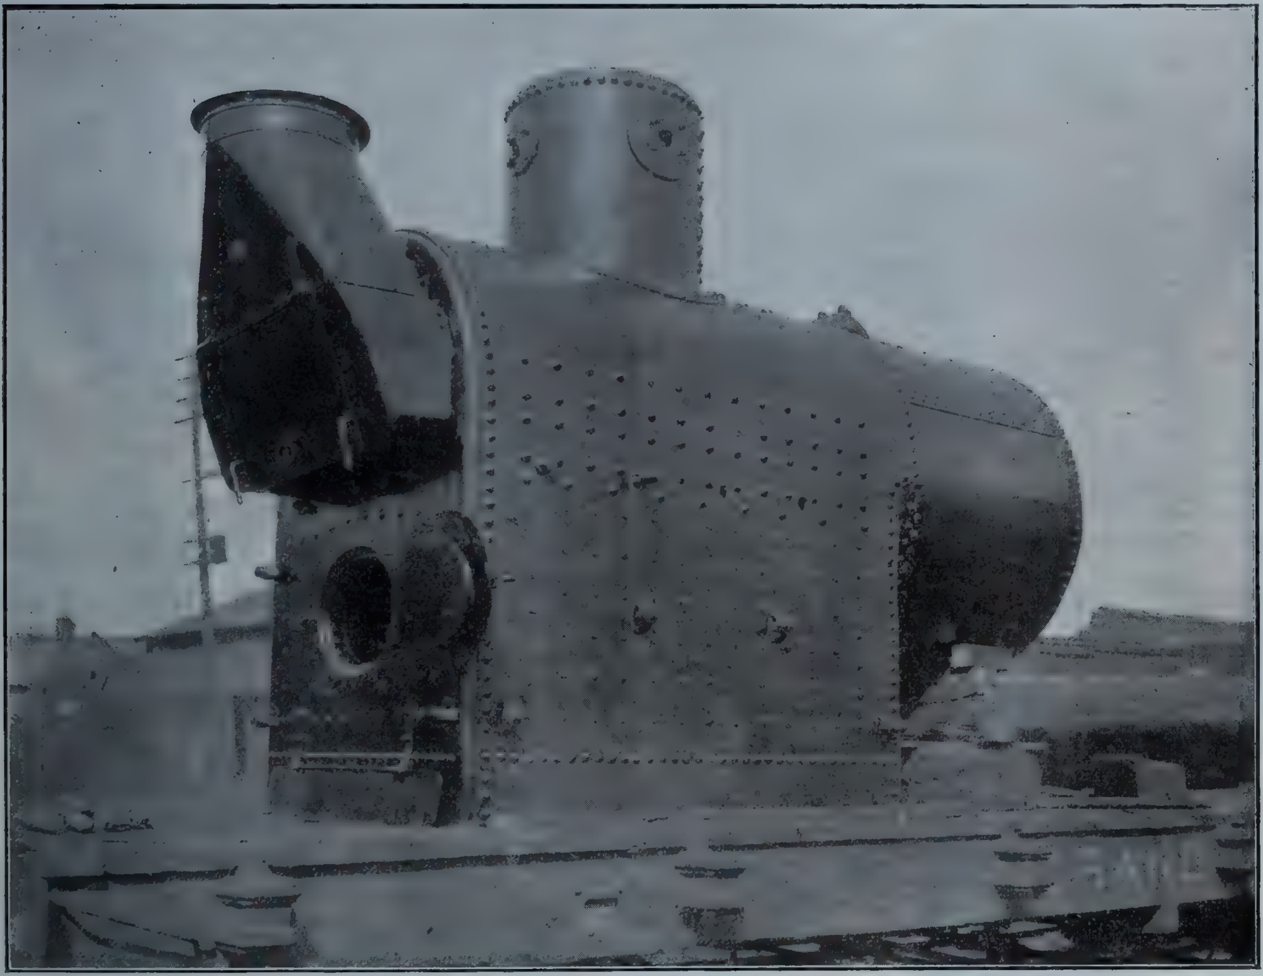
POLSON BOILERS

are built of best quality Flange Steel by skilled workmen.

The photo shows a 58″ square-firebox Marine Boiler that has just been completed by us for the LAKESIDE DREDGING CO.

It is just another example of the popularity of Polson products, amongst engineers and men who know and appreciate good equipment.

Put your plans and specifications up to us.

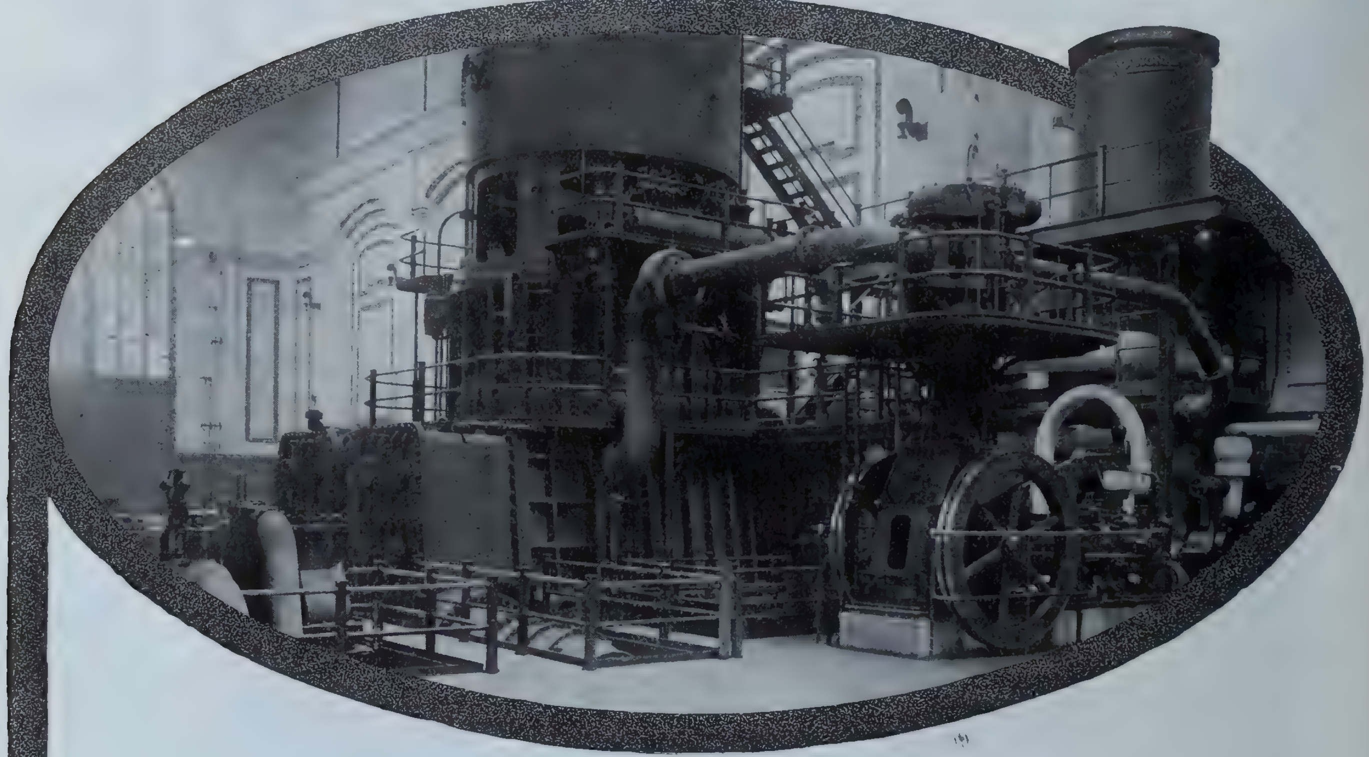


Polson Iron Works, Limited

Toronto, Ontario

In Power Plants such as this you find NATIONAL

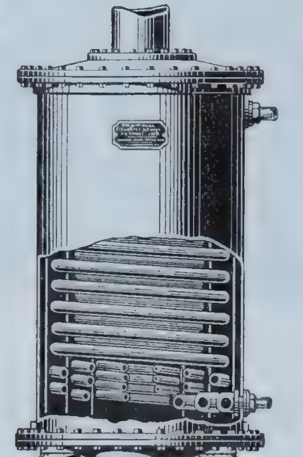
FEED WATER HEATERS



In this well-known power plant, with its big turbo-generators, there are now in operation 40,000 Horse Power of

NATIONAL

Feed Water Heaters



To the man who selects power plant apparatus this is significant—especially when one knows that it is the business of this company to generate and sell power and that it has one of the best equipped testing departments in the world.

Because of the reputation of the Nationals previously installed, the acceptance test in this case was very simple—the National handled all the steam from the big generator when operated at maximum overload.

The new catalogue No. 51 fully describes this feed water heater. Send for it.

Always Remember

Perolin

is NOT a Boiler Compound—it's a GERMAN BOILER METAL TREATMENT

Guarantee

We guarantee **PEROLIN**, the German Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;
2. To prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That **PEROLIN** is not a boiler compound for water treatment, but operates independent of water conditions;
7. The **PEROLIN** preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;
8. The establishment of the **PEROLIN** protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

No matter from what source the feed water is obtained, its chemical composition is continually changing, due to climatic conditions and seasons. In periods of drought the soluble matter increases and water that will not ordinarily produce a heavy scale will cause endless trouble then.

While **Perolin** is used in a similar manner to boiler compounds, the **effect is different.** It works through the cracks in the scale to the boiler metal, and expands, loosening the scale so that it can be easily washed out. It forms a preservative film to which no scale-forming substance can adhere. This film is a good transmitter of heat and prevents pitting, corrosion, etc.

We have a letter from the Bureau of Inspection, Tests and Consultation, stating that **Perolin is harmless to metal.**

To convince you that Perolin will produce results for you, we offer to ship—freight prepaid—a sufficient quantity to **test for 60 days.** If it does not accomplish what we claim it will—return what you have left, and the amount used will cost you nothing. **Mr. Engineer, Perolin will make work easier and more pleasant for you.** Be sure to get your employer to try it. If he hesitates, write us and we'll send him some of the letters we've received from users. They'll change his attitude.

Perolin Company of Canada,
LIMITED

76 Adelaide St. West, Toronto, Ont.

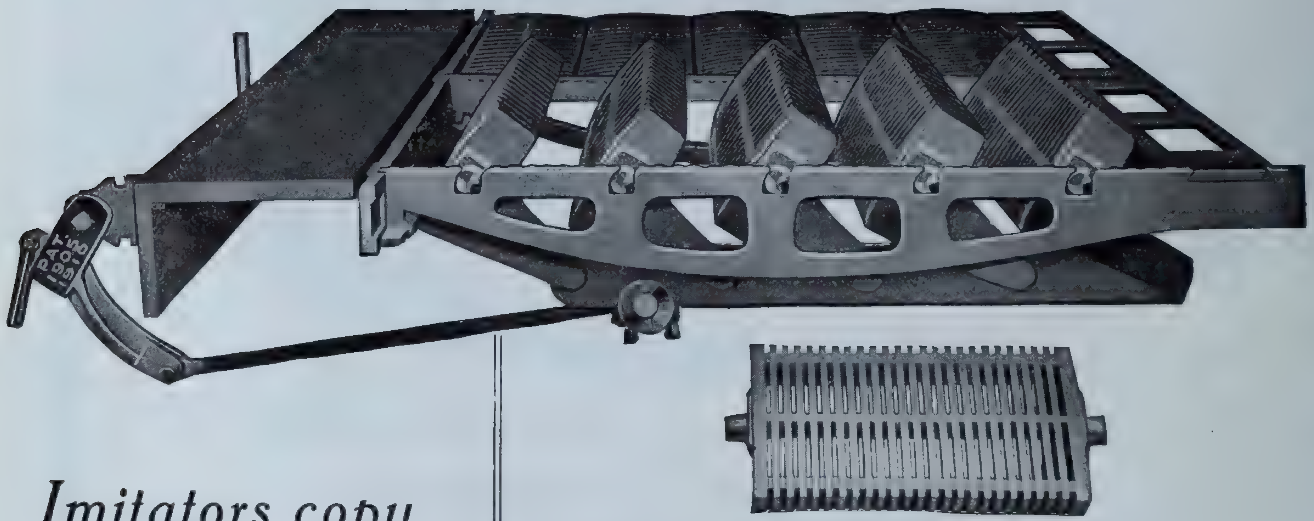
"THE Cyclone"

Shaking and Dumping Grate Bar

Saves Fuel and Labor

We Guarantee

that with the **CYCLONE SHAKING AND DUMPING GRATE** any grade of hard or soft coal, or screenings of same, can be burned with excellent results, both as regards Economy and Capacity, and that the total annual expense to the purchaser for coal, interest, depreciation, repairs, damage to boiler, liability of shut-down, etc., will be much less than will be the case with any type of Stoker or Grate on the market.



Imitators copy only the BEST— Cyclone Grates are imitated.

Thirty Days' Trial

We are prepared to install our grates in the plant of any reputable company on thirty days' trial, leaving it to the purchaser to say if the grate is, or is not, saisfactory at the end of that time. If satisfactory, we will expect payment on the terms agreed on, and if not, we will remove the grate from the premises without cost to the purchaser.

Slight Temperature Variations May Mean Heavy Losses

in many delicate manufacturing processes. If such a process is involved in the making of your product, you realize how vitally important it is that your thermostatic regulator should be absolutely accurate.

"SARCO"

Water Temperature Regulators

Are Good Insurance

against such losses.

Sarco Regulators depend for their action upon a principle that is absolutely positive and unchanging. The action of the thermostatic element depends on the expansion of a sensitive liquid hermetically sealed within a chamber. Into this chamber is inserted a flexible corrugated tube connected with valve-operating mechanism controlling steam or hot water inlet, according to the temperature in the tank or room.

No leaky air-valves, perishable rubber or leather diaphragms, or variable metal disc diaphragms are used in the Sarco. Sarco-Regulators are exceedingly simple and cannot get out of order.

Let us send you a bulletin with diagrams and descriptions of this instrument. Write for it.

We also sell "Sarco" Steam Traps, "Sarco" Smoke Recorders and "Sarco" Automatic Combustion Recorders. Bulletins sent on request.

Stop Blow-outs and Leaks in Pipe Lines by Using GOETZE No. 2 ELASTIC GASKETS

If you start right now to renew with No. 2 ELASTIC GASKETS, you can steadily reduce your renewals until you have brought them almost to the vanishing point.

This is not a mere "claim"—it is backed up by a *guarantee*—in fact the strongest guarantee ever made by a gasket manufacturer.

Think what it means to re-gasket a joint so it will *keep tight for years,* instead of days or weeks. Think of the saving resulting in gasket costs, labor and shut-downs.

What No. 2 Elastic Gaskets Will Do

No. 2 Elastic Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight. Prevent leaks, blow outs and shut-downs. Will practically eliminate renewal expense for gaskets.

No. 2 Elastic Gaskets are for high pressure and super-heated steam lines, but owing to their indestructible nature, are equally adapted to *any and every condition* about a factory, mill or refinery.

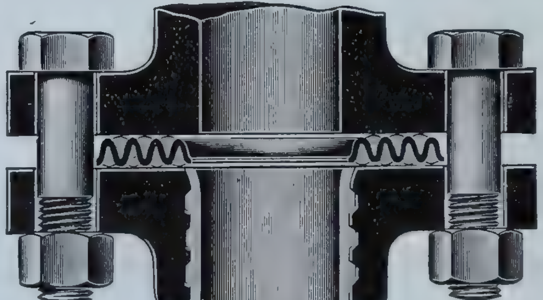
The No. 2 Elastic Guaranteed

Every No. 2 Elastic Gasket is Guaranteed for 5 Years' Continual Service in the Same Joint

There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every No. 2 Gasket whether bought direct from us or through a dealer.

How No. 2 Elastic Gaskets are Made

These Gaskets are made of corrugated copper with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.



Goetze Gaskets are carried in stock by

BENNIS
LONG-LIFE-LINK
CHAIN GRATE
STOKER

More air space is provided to each square foot of grate area than with other makes, and without additional widening of the *actual* air spaces.

The continuous surface of the grate ensures economy in the length of the grate.

By means of the continuous drive, smoothness of running is assured.

The speed of the stoker can be adjusted to a nicety, as there are six variations.

The stoker can be easily hand-fired in case of emergency.

Fine slack fuels can be satisfactorily burnt.

SMOKE MEANS WASTE

Apparent to all but the one most concerned

WASTE
SMITH Co
COAL BILL
He Runs A Gas Producer—But He Wastes The Gas
He Has His Sign Wrong—It's A Smoke Factory
Yes, There's A Fine Bunch Of Profits Going Up That Stack
I'm Glad We Don't Work Down Here. Think Of All That Soot
Suggested by M C Huyche
POWER

This cartoon—by "Power"—is self-explanatory; it is a showing of a "Manager" kicking about "Coal Bill" and ignoring the wasteful condition of boiler-plant equipment.

Smoke is a sure indication of waste of heat—money—value of coal fuel.

Determine 20 per cent. of your annual coal bill, and you will approximate the dividend-earning power of money investment required for **Murphy Automatic Smokeless Furnaces.**

MURPHY IRON WORKS, DETROIT, MICH.
BUFFALO, N. Y.

Smoke Elimination Is Profitable

"A smoky chimney **does** mean a busy plant, but a smokeless chimney means one **just as busy,** with 12 to 15% higher efficiency from the coal used."

In hundreds of cases Jones Stokers have eliminated smoke and at the same time have so raised the efficiency of the boiler plant that a 15 to 25% saving has been effected.

Jones Underfeed Stokers are playing a leading part in the great smoke abatement crusade which is sweeping the Country—**and are paying a good big dividend to their purchasers** as well.

They will save money in your plant, too.

What J-M Boiler Preservative Will Do

It will remove scale already formed in a boiler.
It will prevent more scale from forming.
It will prevent the formation of scale in any water, in any locality, and under any temperature.
It will stop pitting and corrosion.
It will prevent injury to boilers from water containing sulphur.
It will remove oil and grease.
It will stop minor leaks in boilers.

What It Will Not Do

It will not injure iron.
It will not evaporate from boiler.
It will not affect the engine packing or lubricants or the products of a plant which may come in contact with the steam.
It will not cause boiler to foam or prime.
It will not cause any kind of trouble.

Send for Free Trial—

It Must Remove Old Scale and Prevent New Scale or it Costs You Nothing

We will send you one drum of J-M Boiler Preservative for a 60-days' trial. If it does not do as claimed when used according to directions, we will make no charge.

J-M BOILER PRESERVATIVE

is different from others—its action is mechanical and natural, as well as chemical.

J-M Boiler Preservative is attracted to the plates and tubes of a boiler—gets under the scale and loosens it, so that the scale is readily washed or blown out. It then forms a coating to which scale-forming elements will absolutely not adhere.

Our claims are based on experience. We cannot afford to injure the reputation we have built up in the last half-century.

Fill out the attached coupon and mail to our nearest Branch to-day.

Wheeler Condensers are celebrated throughout the world; the Wheeler Condenser and Engineering Company was one of the first companies to concentrate its entire energies on the design and manufacture of Steam Condensing machinery.

For Steam Engines, the simplest, most efficient and reliable outfit is a Wheeler-Admiralty Surface Condenser mounted over combined direct acting air and circulating pumps.

For Steam Turbines, the highest possible vacuum must be attained. Wheeler High Vacuum Surface Condensers are furnished with large capacity centrifugal circulating pumps and the Wheeler Edward Air pumps, The Wheeler Dry Air pump or the Wheeler Turbo Air Pump. **Vacuums of 28 to 29 inches and more are assured.**

Wheeler Products include Wheeler Surface Condensers as outlined. Wheeler High Vacuum Jet Condensers, Wheeler Barometric Condensers, Wheeler Centrifugal Pumps, Wheeler Air Pumps, Wheeler Feed Water Heaters, Vacuum Pans and Multiple effects, Wheeler Barnard Forced Draft Cooling Towers, Wheeler Balcke Natural Draft Cooling Towers and other products.

For Small Floor Space

For Small Generator

ROBB VERTICAL COMPOUND ENGINE

High Speeds of Rotation with pistons of large diameter give a powerful engine in small space. The direct-connected generator can be of small diameter because of the high speed so that the unit will be of relatively low cost and small dimensions for a given kilowatt output.

Quiet and satisfactory operation at piston speeds of only 500 to 800 feet per minute make these engines particularly adapted to electric light plants and electric railway service—installations requiring high-grade durable engines which will operate under a great variety of load.

Long periods of operation without attention are made possible by the system of forced lubrication which supplies all bearings with an abundance of oil.

Complete enclosure of all moving parts prevents oil from flying about and protects the parts from accidental injury.

Low Steam Consumption is due to the very small clearances, high speed, automatic governing, and refinement in finish.

Ask for Bulletin No. 201.

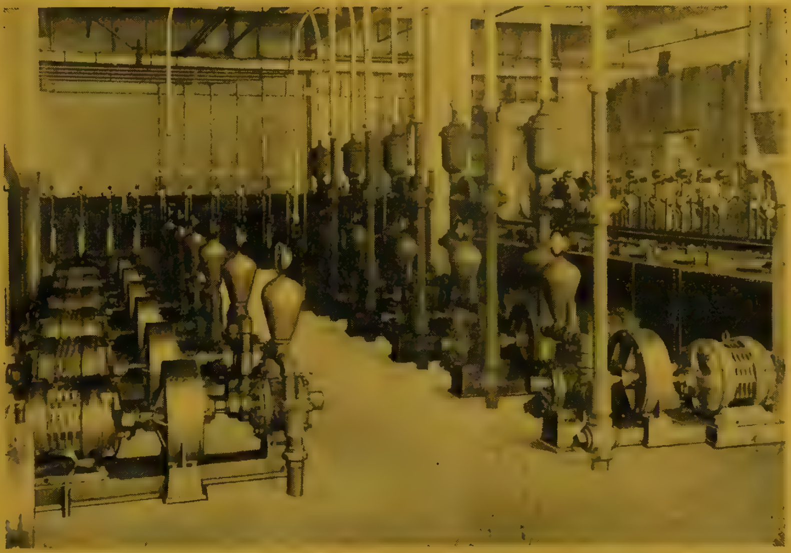
Where Oil Efficiency and Economy Spell Dollars

When concerns like the Indiana Steel Co., National Core Co., National Cash Register Co., Singer Mfg. Co., Westinghouse Elec. & Mfg. Co., etc., use

BOWSER
ESTABLISHED 1885

Systems for safe, convenient and economical handling of lubricants, paint oils, varnishes, etc., it is because they are *Money Savers.*



One small part of Bowser Equipment as installed in the Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.

From 50 to 14½ Gallons Per Month

There's a sample of Bowser saving in New York City. Bowser can give you hundreds of other just such instances elsewhere.

And Bowser can show you just how this same economy and efficiency can be applied in *your* plant.

Bowser Will Surprise You

Some power plant owners have said "It can't be done." Bowser has shown them where they were wrong.

Put your oil problems up to Bowser—let him assist you in getting a full dollar's worth of service from every dollar's worth of oil—how to use the same oil over and over again—how at "heaviest load" seasons, to make every engine and machine work "at normal" because of *increased oil efficiency.*

Accuracy Compellers

But what is more, learn how Bowser systems *compel* accuracy, economy, tidiness, efficiency, safety, where your oil is concerned. No charge for asking. For twenty-nine years Bowser has been solving oil storage problems.

To get something of the Bowser scope write for the Bowser Oil Filtering Book. Ask questions. No obligation.

Should be read by Buyers, Managers, Superintendents, Foremen and Engineers

The "BELTING MANUAL" fresh from the press tells how to:—

Install belting.
Care for belting.
Repair laps.
Make belts endless on the pulleys.
Lace belts.
Clean belts.
Remedy some of the belt troubles.
Find the widths and lengths of belts.
Find the horse-power of belting.
Find the speed of belting.

The fifteen pages of mechanical rules and tables are unusually complete and compiled expressly for use in solving the daily problems of Power Plant practice.

In short, the "Belting Manual" is a veritable fund of practical belting information—the latest and most authentic book of its kind.

Just take a minute to send the Coupon—to-day.

WHAT CLING-SURFACE IS

A 12-inch laminated belt driving an air compressor in John Bertram & Sons plant (also the Canadian plant of Pratt & Whitney). Although the variation of load, sometimes sudden, between 25 and 82 horse power, makes this a severe test for Cling-Surface treatment, the belt had run for two years with 24 inches of sag under full load without slipping.

Driver pulley, 14-in. diameter, 765 revolutions per minute. Driven pulley, 5-foot diameter. Distance between shaft centres, 13 feet. Belt speed, 2,800 feet per minute.

Belts are made of perishable animal or vegetable fibre.

They are compelled to run in the hot, dry air of factories or damp air of other plants, at the speed of a locomotive, pull heavy loads under constant strain, bend back and forth many times per minute, and do their day's work.

What happens?

When they are new they do fairly good work, but soon they begin to dry out and polish. This causes slipping. The more they slip the more they polish, and sooner or later burn, and crack.

The two usual methods of preventing slip are: First, by tension (tight belts). Second, by putting on some sticky material.

The first way loads your belts, bearings, shafting and engine with a great dead drag of friction load. It is a most wasteful way.

The second way hurts your belts, dries them out, uses up power to rip the belt off the pulley and often forms lumps, on top of which the belt rides, with loss of contact and breaking the suction of belt on pulley. Also a wasteful way.

Both are poor ways.

Cling-Surface is a better one—the modern one.

Cling-Surface is a special, preservative food for leather and cotton belts, and also helps good rubber or balata. It contains no rosin nor other harmful ingredients, and is not sticky.

You feed Cling-Surface slowly to a leather or cotton belt, and it penetrates **into the body** of the belt itself, the pulleys force it in, the pores suck it in. It fills and surrounds every tiny fibre, inside and out, with its clean, neutral, lubricating food; so that these fibres work with their neighbors in little preservative, frictionless bearings—not the usual rubbing of dry fibre on fibre (and it does the same for ropes as for belts). It gives to the belt face a velvety softness and smoothness, while it makes the belt body elastic and flexible, mellow and healthy **all through.** The face is like the best new calfskin, giving absolutely perfect contact on the pulleys, while the body behind is in the best possible condition to follow and grip the pulley, because it is so flexible, firm and vigorous. And it stays so.

Such belts will never dry out, will never crack—you cannot make them stiff and dry.

They are fume-proof, water-proof, trouble-proof.

For rubber and balata belts it refreshes their surface, and gives them a better pulling face than they ever had, even when new.

This is what Cling-Surface is, and part of what it does.

The next page and the photographs herewith tell more of what it does.

Cling-Surface
the life preserver for belts

Cling-Surface
the life preserver for belts

WHAT CLING-SURFACE DOES AND WHO USES IT

"We have been using Cling Surface for about eight years, with most satisfactory results. Have used it for all kinds of drives. It lessens tension, increases efficiency and period of usefulness. Not a sign of slipping."
T. S. SIMMS & CO. Limited, St. John, N.B.
H. H. Reid, Sec'y. and Treas.

An excellent example of Cling-Surface results in the Canadian Rand Drill Company shops, Sherbrooke, Quebec. First treated with Cling-Surface in Jan., 1900. One year later, it had 20" slack, and to-day, over 11 years later, it is in perfect condition. No slipping.

GUELPH LIGHT & POWER DEPARTMENT, Guelph, Ontario. "This shows one of our main belts which has been treated with Cling-Surface for 8 years. No slipping. Cool bearings."
J. J. HEEG, Chief Engineer.

We have told you what Cling-Surface is, and that it puts and keeps the belt in mellow, flexible vigor, so that the whole belt lies close down to the pulley face and the whole belt takes the strain of the load. Cling-Surface keeps the belt in such condition that it can do its best work and last.

Then it makes it work by stopping all slipping. It stops the slipping better than tension does, and the tension is not necessary for this purpose. A belt which does not slip does not have to be run tight, but can be run slack, and the slacker it runs the more of the pulley it wraps. The greater the pulley contact the greater transmitting capacity the belt has.

By preserving your belts and preventing their slipping you have then secured the two essentials of perfect belt service. As a result, many economies are possible and must follow:

First: Increased power. Power which was lost in overcoming friction produced by belt tension is compelled to produce *output*, while no power is lost in slipping. Your machines run faster and more evenly.

Second: Oil. Slack belts tremendously reduce friction on bearings, and less oil is required. No hot boxes.

Third: Lacing. When belts do not have to be tightened, the amount and cost of lacings is greatly reduced, while the laced leather lasts longer.

Fourth: Fuel. Fuel is saved because the friction load is reduced with slack-running belts.

Fifth: Time and repairs. Time used and money spent in belt tightening and repairs is greatly lessened. What is even more important, expensive help and valuable machines need not stand idle while such repairs are being made.

Sixth: Worry. Cling-Surface-treated belts are dependable. They are always in condition to do their work, and can be trusted when a rush job and peak loads come on. That source of worry is done with.

Cling-Surface has been used by the best concerns in Canada for nearly a generation, and its value has long been established. By not using it you are losing what for years has proven profitable to others.

Among such concerns are: Massey-Harris Co.; Waterous Engine Works; Crossen Car Co.; Toronto Paper Mfg. Co.; Canadian Westinghouse Co.; Dominion Canners; Sawyer & Massey Co.; Steel Co. of Canada; Mickle, Dyment & Son; McCormick Mfg. Co.; Canada Iron Corp.; Canada Sugar Refining Co.; American Cyanamid Co.; Canadian General Electric Co.; Algoma Steel Co.; Frost & Wood Co.; Dominion Sewer Pipe Co.; Gurney Foundry Co.; Gerhard Heintzman, Ltd.; Hiram Walker & Sons, Ltd.; Canadian Pacific R. R.; Grand Trunk R. R., etc.

These concerns and many more know and use Cling-Surface. You will not know its value until you have tested it.

We are ready to ship you a package on approval and guarantee results to be satisfactory to you in every respect. Plants in the North-West can buy Cling-Surface locally if they will ask us the nearest point of stock.

Write us now for such a trial lot.

MORRISVILLE, PA. 15

The Original Large Main Shaft Drive The Morse Silent Chain Drive shown on the opposite page is particularly interesting in that it was the first large main shaft drive of this type installed, and, although it has been in daily service for the past ten years, has required no repairs of any kind

This drive is located at Morrisville, Pa., in the plant of the Vulcanized Rubber Co. Complete details follow:

200-horsepower drive (shown running), from Corliss Engine to jack shaft. Two chains, each 6 inches wide, 1½-inch pitch, speed 1150 feet per minute. Sprockets, 95 and 95 teeth, 85-inch centers, speeds 97 and 97 R. P. M.

200-horsepower drive (shown running), from jack shaft to line shaft. Three chains, each 6 inches wide, 1½-inch pitch, speed 715 feet per minute. Sprockets, 59 and 95 teeth, 169 inch centers, speeds 97 and 60 R. P. M.

Regarding this drive, Mr. George Hill, Consulting Engineer of New York City, under whose direction it was installed, wrote shortly afterward as follows:

"The reduced center distances incident to the use of the chain permitted reducing the floor space in the engine room some 750 square feet, which amounted to a saving in the cost of this building of one thousand ($1,000) dollars, making a difference in the cost of the chain and belt drive of about five hundred ($500) in favor of the chain. * * *

"The nature of the work in a rubber mill is one that constantly brings sudden shocks on the transmission gearing, but notwithstanding this, no link or tooth wear, or perceptible lengthening has taken place in these main driving chains since the starting up of the mill in October 1903, and a joint pin removed shows practically no wear on the rocking surfaces. * * *

"The speeds of these chains are about 1150 feet per minute, and they have required but little attention in the way of lubrication, and make practically no noise when running. * * *

"While not quite time enough has elapsed (this article was written some years ago) to substantiate all the claims made by the makers, careful inspection of the chains running shows them to be giving perfect service, and this has persuaded me to use the Morse Chain for other contracts, as commercially they are the cheapest if a period of five or more years is considered."

Morrisville, Pa.

"750 square feet reduction in floor space"
"$1000 saved in the cost of building"

by using

Morse Silent Chain Drives

Such is the initial record of the above 200 h.p. drive.

In the more than ten years of its service, the entire first cost has been saved in power alone three times over, yet the attendance cost has been minimum and the repair cost nil.

Your copy of Booklet 12-B, showing applications in many different fields, will be sent free on request, together with any special information desired regarding your own transmission problems.

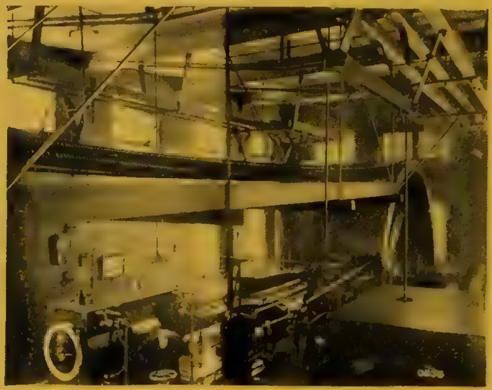
Let us figure out a probable saving in your plant.

Morse Chain Company, Ithaca, N.Y. B-11

A Simple Twist Tightens Any Rope

No. 95/26
Hunt Tension Adjusting Coupling spliced in the rope ready to put on the drive

If one of the bands on your multiple rope drive stretches, do you resort to the old-fashioned method of cutting out a piece of rope and resplicing it?



No. 0835.
1000-H.P. Rope Drive, equipped with Hunt Tension Coupling Bands.

All this is unnecessary if your drive is equipped with Hunt Tension Adjusting Coupling. A simple twist of the coupling tightens up any individual band and makes each rope do its share of the work.

If interested in learning more about these couplings and Hunt Stevedore Rope, with its unique system of internal lubrication that prevents wear and increases its efficiency, ask for a copy of our catalogue J 12.8 "Manila Rope." It contains 50 pages of information on rope drives for engineers.

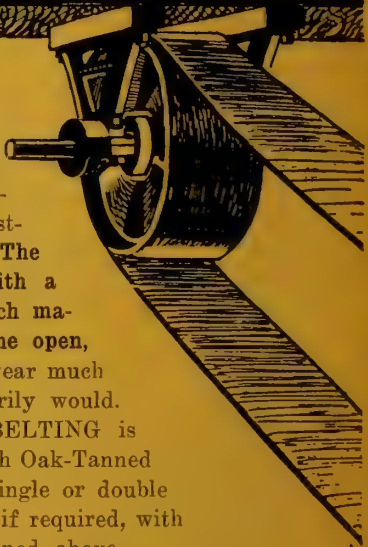
J.D.McArthur's LEATHER BELTING



Will Lower Your Transmission Cost

Our SAFFRON TANNED BELTING is especially valuable on fast-running machinery. The splices are stitched with a waxed thread lock-stitch machine—they cannot come open, and cause the belt to wear much longer than it ordinarily would. Our OAK-TANNED BELTING is made from Prime British Oak-Tanned Leather. Splices of single or double belting can be stitched, if required, with the machine as mentioned above. This splice and the high quality of our beltings mean that the buyer will effect big yearly savings.

Let us give you full particulars. Write!

J. D. McArthur & Company

Brockville, Ontario

How Much is Your Power Loss Annually?

In the big Canadian plants where *Efficiency* methods are being effectively employed to *check* leakages, this is the question that is being given the most *serious* consideration. Because it has been found that such losses—which in many instances reach *astounding figures* — are due, mainly, to *indifference* and lack of *care* in the selection of suitable belting.

Your Loss or Your Gain Depends Upon Your Belting

That is what gives importance to this—our message to you.

For over half a century we have been producing Rubber Beltings that have become the *standards* by which other beltings must be judged.

We have studied the power transmission question from every angle and brought to bear upon it the experience, brains and skill of our *experts*—familiar with actual working conditions—and the resources of *largest* and *best* equipped plant in Canada.

And we have produced four grades of Power Belting that are 100% efficient in *Reliability* and *Service* in Power Transmission.

"PARA" "KEEWATIN"

"LUMBER KING" "COLUMBIA"

These are the beltings used wherever *efficiency* is the first consideration—wherever Beltings are bought on their *merit*.

Every step in their manufacture is governed by the *prudence* and *experience* of a lifetime—plus the *unwavering* determination to produce beltings that would measure up to every *Service* test.

If You Are Not Getting the Service You Expected From the Beltings You Buy, Get in Touch With Us. We Can Help You—And We Know How.

BELTING

Excels all others in economy, strength, efficiency and true running, whether for Transmission of Power or Conveying.

A test recently made at McGill University, Montreal, of 6-ply "Maple Leaf" Belting, light double leather, and 6-ply rubber, showed that our "Maple Leaf" stood a breaking strain 50% greater than the leather, and 25% greater than the rubber belt.

A trial belt will convince you.

Here is an example of what backs up our claim that

"Our Belting costs less per day of Service"

The big belt in the circle, a 24-inch double belt, 133 feet long, was bought from us in 1878—thirty-six years ago: since then it has been in continuous service, as the main drive in a flour mill. In October, 1913, after thirty-five years "on the job," a new belt replaced it, and the old belt was converted into the five smaller belts shown in the lower photo, one 12″ x 85 feet long; one 7″ x 98 feet long; one 6″ x 89 feet; one 4½″ x 50 feet; and one 4″ x 38 feet 10 inches. Service like this makes the first-cost-per-foot-length insignificant. SERVICE, and service ONLY, is the true criterion of belt value.

Facts, like the case cited above, prove the downright service in our belting.

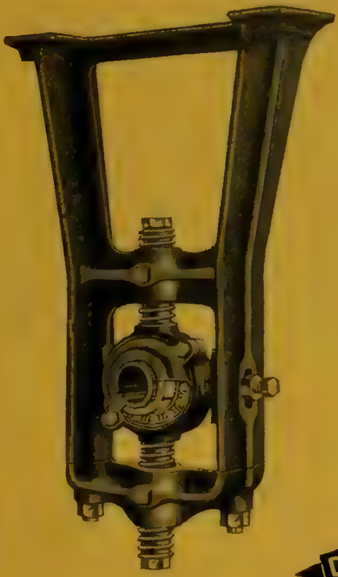
☞ To Ensure Satisfaction—State Where Belt is to Run

Transmission Appliances with a Reputation for delivering the power with Maximum Efficiency.

Universal Giant Hangers

alone combine absolute universal adjustment with symmetrical design and unusual strength, all requirements of a perfect hanger.

Large cast iron plungers make them self-adjusting and insure perfect alignment with the shaft.



Skefko "S.K.F." Ball Bearings

are the only absolutely self-aligning ball bearings made. They conform to the deflection of the shaft without binding. Maximum load-carrying capacity is secured by the double row of balls, which provide three balls at all times to carry the load.

Fairbanks Wood-Split Pulleys

The pulleys with the web built into the arm and rim, a feature which absolutely prevents the separating of the rims from the arms. The Rims are built up of segments of properly kiln-dried basswood.

Dick's Balata Belting

An ideal belt for all service; its stronger gripping powers insure positive transmission of the whole power. The saving in power thus secured will pay for the belt many times.

We carry in stock the most complete line of transmission supplies, steam goods, etc., in Canada.

Saskatoon Calgary Edmonton Winnipeg Regina Vancouver Victoria

Canada's Departmental House for Mechanical Goods

A Typical LEVIATHAN Main Drive, Installed at the Plant of The Riviere du Loup Pulp Co., 24 in. x 6 ply, 81 Feet in Length.

LEVIATHAN BELTING

Has been sold on a "make good" basis for over thirty years. If it hadn't made good we would have been out of business long ago. The fact that our business is progressing rapidly is ample proof of the merit of this belting.

With every belt we guarantee full value in service, dollar for dollar, horsepower for horsepower, and just as we have figured our tables of horsepower for the best results, just so in making the above statement, we not only expect to give equal service, but **better service, and more economically.**

THE REASONS WHY:

LEVIATHAN has far greater tractive power.

LEVIATHAN can be run much slacker than leather, thus putting less strain on the journals.

LEVIATHAN is not affected by atmospheric changes.

How Do You Buy Belting?

Do you buy "just belting?"—or do you *invest* in the *service* that is to follow?

There's a big difference.

Belting bought on "price" alone is a poor investment. When trouble comes to such belting the first cost is increased by "idle machinery, repairs, salary for idle men, loss of output, etc."

Then, if you "keep tab" on your belts you will know just how much that "belt bought on price" has really cost you.

GOODYEAR

Belting For Every Purpose

Goodyear Belting solves all problems. We make 240 different sizes and kinds at our great Bowmanville plant.

Among them is just the particular belting for your particular needs.

Transmission

These are made for maximum power delivery. They cling to the pulleys so that slipping is practically eliminated.

Goodyear Belting cannot stretch. That is because all the "stretch" is taken up in course of manufacture. Hence no idle machinery due to slackened belts that must be "taken in."

The fabric used for the filler and warp of Goodyear Belting is best cotton duck. We test it in our laboratory like all other Goodyear materials. Only the strongest and best by actual test is selected for Goodyear Belting.

Conveyor and Elevator Belting

Goodyear Conveyor Belts are made strong enough to stand up under heaviest loads, and year in and year out constant service.

Goodyear Elevator Belts for ore and grain are made to carry the heaviest buckets.

Tell Us Your Belt Needs

Put your Belting problems up to Goodyear. This service is free. Let us tell you of just the Goodyear Belting for your very purpose—and why! We can save you money. Buying belting this way means maximum service—belt insurance.

Single Arm Steel Split Pulley

Dodge Steel Split Pulleys

This is something new—and admittedly the most perfect Steel Split Pulley on the market.

Rims ¼ in. steel—cannot dent, bend or break.

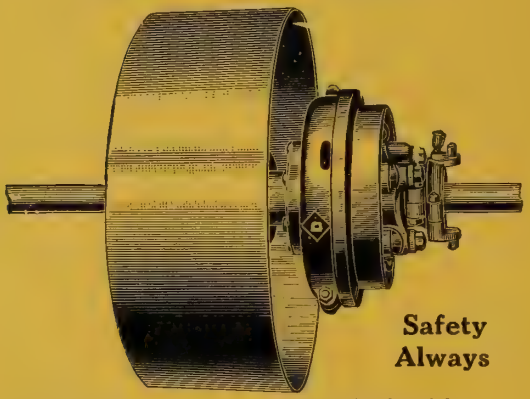
No grooves through centre to decrease belt adhesion. This seamless and beadless rim is strong and true running.

Arms support rim on either side of parting.

Order a sample pulley for comparison of quality and price.

Double Arm Steel Split Pulley

Dodge Friction Clutch



Safety Always

This Friction Clutch cuts off power in the nick of time—thus putting your men and machines on the safe side.

It can be put up or taken down without disturbing other equipment. Can be used as a cut-off coupling, for driving pulley or rope sheave, or for attachment to quill carrying a main driving wheel.

Can you afford to have machines idle while repairs are being made, or employees suing for damages on account of injury?

Full particulars in our "POWER TRANSMISSION ENGINEERING" CATALOG.

Dodge Hangers are smooth road-beds for power.

Dodge Bearings reduce friction because there is a true ball and socket connection between the bearing and the frame in Hangers and Pillow Blocks, which permits the bearing to freely align with the shaft.

Dodge Hangers and Pillow Blocks are furnished with ring or capillary self-oiling bearings, all lined with a high-grade metal, and BORED and REAMED. One filling of oil will last 3 to 6 months.

Full particulars in our "POWER TRANSMISSION ENGINEERING" CATALOG.

Ball and Socket Adjustable Hanger

To link yourself with

Dodge Products

is to ensure Highest Efficiency and Practical Economy

The Dodge line is one of proven merit. It speaks strongly for itself.
A trial is convincing.

Dodge Wood Split Pulleys

Are balanced and run true. Result of selected, seasoned, kiln-dried stock, combined with skilled workmanship and twenty-seven years of "knowing how."

Over a million in successful operation, and the output each year is greater than the year before.

Your Output Increased With Your Power Bill Reduced

Does This Interest You?

READ THIS REPORT
From a Superintendent and Engineer to their Managing Director

THE VICTORIAVILLE FURNITURE CO.
Manufacturers of Medium Furniture

Mr. J. E. Alain, Managing-Director, Victoriaville, P.Q., Nov. 20, 1913.
The Victoriaville Furniture Company.

Dear Sir:—

Since we have been operating with the Chapman Double Ball Bearings Shafting equipment, we have made a careful study of our cost and efficiency system, comparing the output with our old system versus the Ball Bearing; and have much pleasure in submitting the following report, which should be interesting to any factory using power. You will also note that the equipment of ball bearings installed on our line shafting so eased the load on our power plant through the elimination of friction that the machines were able to run at their proper speed with the following interesting results. These results are **entirely outside** of the saving in power which, in **addition** to the increased production, as shown below, will amount **to over 20 per cent. of the entire power:—**

Linderman Machine:—

The record of this machine on old system of transmission had an output of 2,600 ft. daily, when we are getting with Ball Bearing system an output of 2,800 ft. on the same machine, thus giving us a daily gain of 200 ft. based on direct wages of $5.65 per day, or 2,400 ft. for twelve working days, or a net gain of $5.22 for 12 working days or fortnight.

Planers, 3 machines and one Buzz Planer:—

Lumber ready to go through Sandpapering Machine:—

Old system took 404 hours to finish 49,000 ft., direct wages $31.20. Ball bearings took 390½ hours to finish 54,000 ft., direct wages $31.20. The above will show that we produced 1,210 ft. per day on old system, comparing with 1,380 ft. a day with Ball Bearings. 1,380 multiplied by 12 working days will give a total of 16,560 ft., being the production of twelve days with direct wages of $31.20, or a gain of 26 cents per thousand feet, based on 16,560 ft., will give us a net gain of $4.30 per fortnight.

H. B. Smith's Triple Sander Machine:—

Direct wages on old rate for an output of 21,715 ft. were $18.10, while the direct wages with Ball Bearings on an output of 35,400 ft. were $29.07, thus making a gain of 9 cents per thousand feet, based on 35,400 ft., being a fortnight's output, made clear gain of $3.18 for twelve working days.

(Signed) Frank McDonald, Superintendent.
" Jos. Beaudet, Engineer.

N.B.I.—The above has been referred to our Cost Accountant, and I have much pleasure to confirm the same.

(Signed) J. E. Alain, Managing-Director,
The Victoriaville Furniture Company.

Over 2,000 Canadian Factories are getting similar results. Can YOU afford to operate without Chapman Double Ball Bearings?

No trouble to change over—Our Bearings suit any standard Hanger.

Our Double Ball Bearing **LOOSE PULLEYS** will operate perfectly **WITHOUT LUBRICATION OR ATTENTION, EXCEPT A LITTLE VASELINE ONCE A YEAR.** Your loose pulley trouble will be a thing of the past.

Write us for particulars and let us figure with you on an equipment of Chapman Ball Bearings for your plant.

Power Plant Equipment, Harris Abattoir, West Toronto

Staff Article

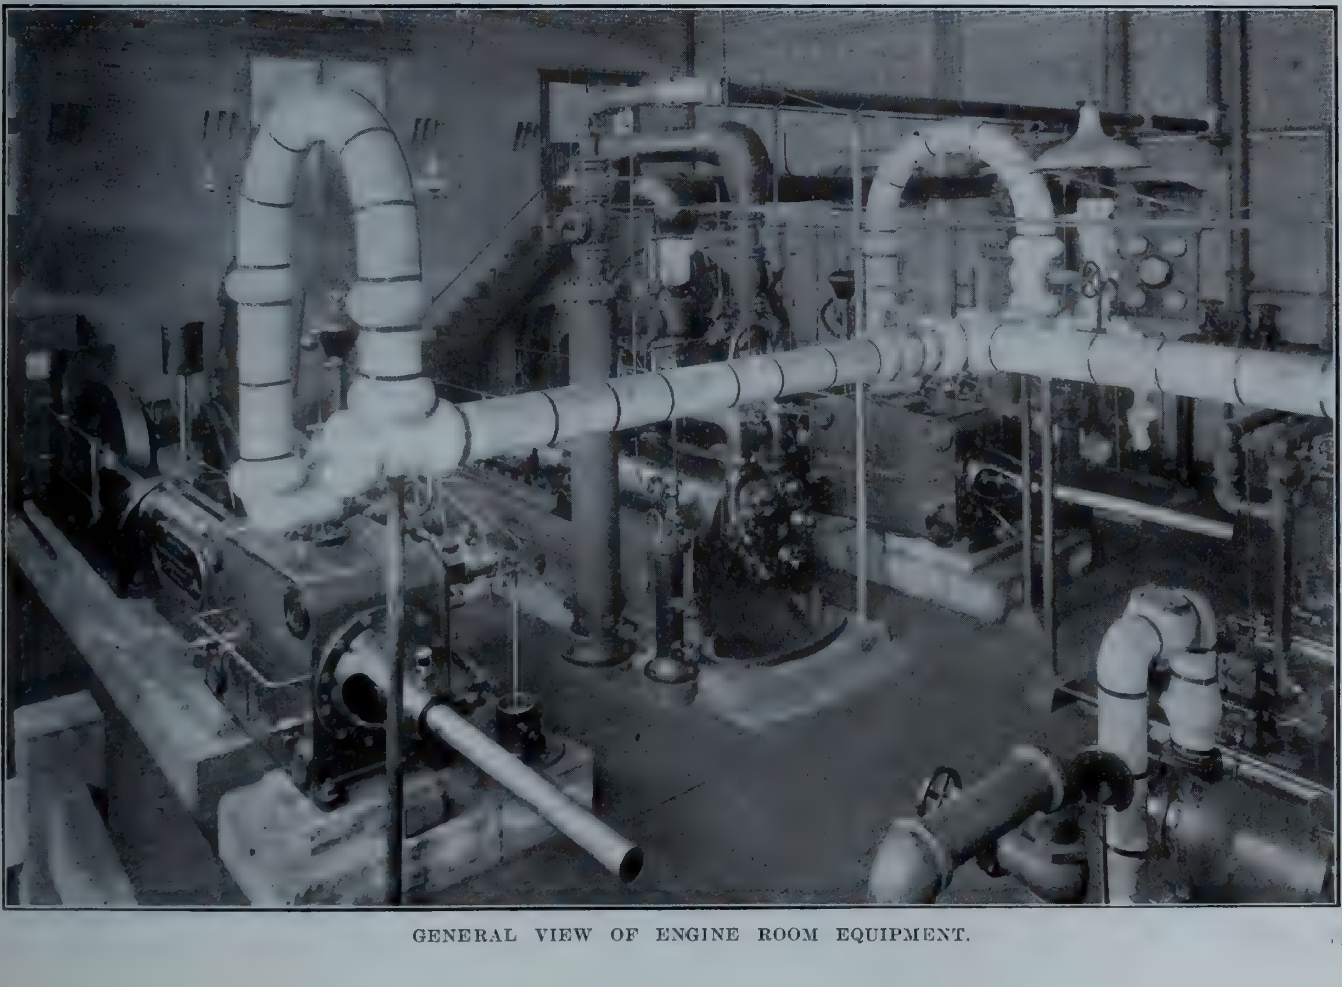
The Public Requirement of an Abattoir or Packing House is That Absolute Cleanliness of Method, Equipment, Interior and Exterior of Buildings, Habits and Actions of Employees, be the Prevailing Conditions Under Which Work is Carried on. The Management Requirement is that the Power Plant on Which the Industry Depends for its Source of Action, be Kept in Such Perfect Condition of Repair and Tidiness, that the Risk of Breakdown and Delay is reduced to a Minimum. A Shut-down in Summer in Plants of this Nature Means Invariably Considerable Loss, and in the Harris Installation, it will be Noted, Not a Little Foresight Has Been Displayed as a Preventive.

THE Harris Abattoir Co. recently started operations at their new plant, West Toronto. It is one of the best equipped for its particular purpose in Canada. The buildings, constructed of reinforced concrete with brick "curtain" walls and concrete floors, are arranged in two separate units, that on the west side being the abattoir and on the east side the cold storage building. Between the two blocks are tracks connecting with the railway in the north side of the property, while on the south side is a shipping platform extending the full length of the buildings. The power plant is situated in the west block where is also the can ice plant, while the cool rooms are in the east block with the offices adjoining.

Boiler Room.

The boiler room is a lofty brick and concrete building, 50 x 50 ft. In it are installed three Heine water tube boilers supplied by the Heine Safety Boiler Co., St. Louis, Mo., and erected by Mr. T. J. Main, Toronto. The boilers are each rated at 300 h.p. and are capable of being operated 50 per cent. overload. The working pressure is 150 pounds. They have "Dutch Oven" furnaces and Murphy mechanical stokers, each furnace being equipped with an Ellison differential draft gauge fitted above the fire-door. Each boiler is equipped with a soot blower furnished by the Baylie Soot Blower Co., St. Louis, and also with a patent high and low water alarm.

A very complete coal and ash handling plant has been installed. A spur from the railway tracks runs up to the boiler room, and the coal is dumped from the cars to bunkers below the tracks. The bunkers are below the boiler room floor level, which is again 10 feet below the ground line. The coal is carried from the bunkers by a vertical bucket conveyor to the top of the boiler room and discharged through spouts to two coal hoppers situated above the furnaces. The hoppers have a capacity of 40 tons of coal each, and have on the underside a swinging spout which enables the coal to be distributed with greater facility. At the bottom of each hopper is a door for controlling the amount of coal delivered to the scales where it is weighed before being put on the furnaces. The ash conveyor carries the ashes from the back of the boilers, under the boiler room floor and up to



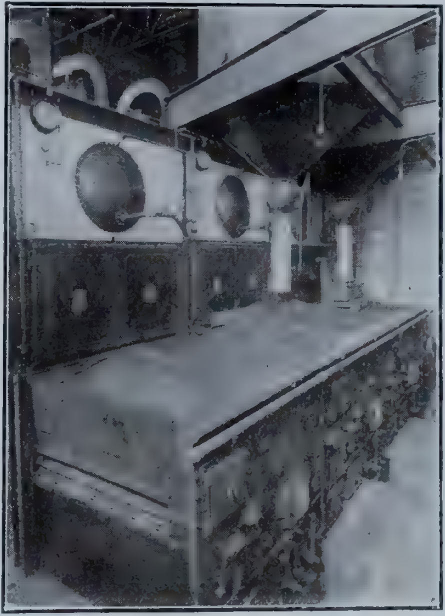
GENERAL VIEW OF ENGINE ROOM EQUIPMENT.

the tracks outside. The ashes are drawn from under the fires at the back of the boilers, in the basement, and put on the conveyor. In this conveyor system, the coal is only handled once, that is when it is being distributed over the furnace, and the ashes only once, when being put on the conveyor. This arrangement makes it possible to keep the boiler room clean and orderly as well as being a great saving of labor.

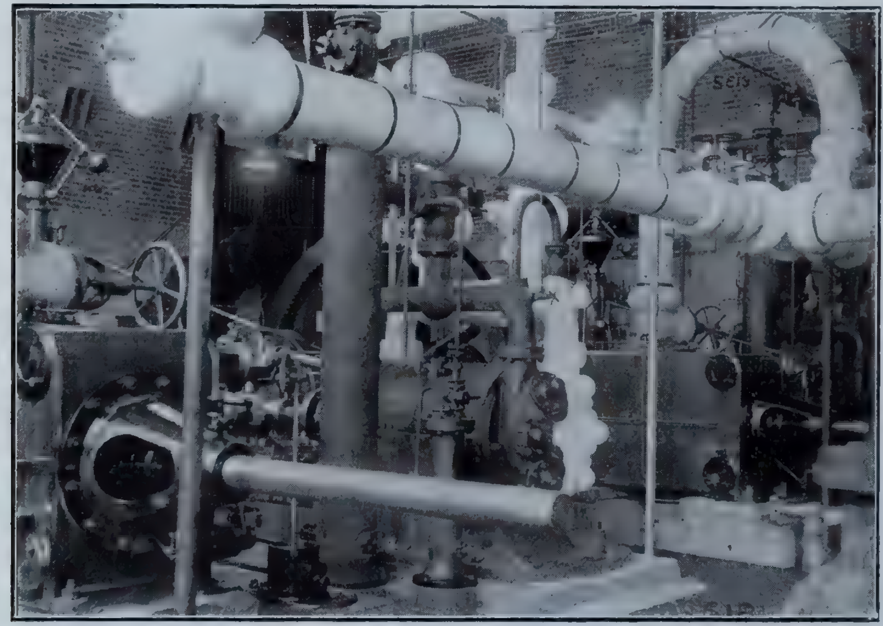
The main boiler header is 10 in. diameter, the branches 6 in., and the main steam pipe 8 in. diameter. All the steam pipes are covered with 85% magnesia compound supplied by the Canadian Johns-Manville Co., Toronto. The steel smoke stack is 6 ft., diameter and 150 ft. high. Tests are taken weekly with a "Hays" CO_2 recorder, the apparatus having been supplied by the Combustion Appliances Co., Chicago, Ill.

Pumping Installation.

The engine room is of the same size and construction as the boiler room and on the same level. Along one side are located the feed-water heater, boiler feed pumps and hot and cold water service pumps. The heater is of the "Cookson" type, having a capacity of 1,000 h.p., and was supplied by the Bates Machine Co., Joliet, Ill. There are two boiler feed pumps supplied by the Smart-Turner Machine Co., Hamilton. These are both 10-6-12 in., with pot valves and outside packed plungers, and deliver water to the boilers at about 200 degrees F. The hot water service is taken care of by a Mather & Platt type turbine pump having a capacity of 150 U.S. gallons per minute against a head of 185 ft. and direct connected to a C.G.E. 15 h.p. induction motor, 550 volts a.c. running at 1,450 r.p.m. For the cold water service, there are two pumps both of the same capacity and type, but driven by a steam turbine and motor respectively. The pumps are of the centrifugal type and have a capacity of 400 U.S. gallons per minute against a head of 125 ft., when running at 1820 r.p.m. A Terry steam turbine is direct connected to one pump and a 20 h.p. motor drives the other. The pumps and motor were supplied by the Canadian Allis-Chalmers Co., Toronto, and the turbine by the Hare Engineering Co., Toronto.



BOILER ROOM, SHOWING STOKER INSTALLATION.



LINDE-BRITISH COMPRESSORS AND "LEONARD" ENGINES.

In the basement under the engine room is an 18-16-12 in., Underwriters' steam fire pump having a capacity of 1,000 gallons per minute at 70 r.p.m. This pump was supplied by Canadian Allis-Chalmers Ltd., and is connected to a system of standpipes and also to the sprinkler system. Adjoining the above are two Smart-Turner Vacuum pumps 6½-7 in. for returning the drains from the heating system to the feed water heater. The hot water tank is situated near the pumps.

Switchboard.

The switchboard is located in the engine room and consists of four black slate panels, arranged in two sections, for power and lighting respectively. Each section has an instrument panel and a feeder panel. The current is taken from the Interurban Electric Co.'s mains and is stepped down from 22,000 volts to 550 for the motors, by three Crocker-Wheeler 300 k.w. transformers and to 110 volts for the lighting circuit by two Canadian Westinghouse 35 k.w. transformers. There are 40 motors installed throughout the plant, varying in power from 1 to 35 h.p.

Ammonia Compressors.

In the engine room are two ammonia compressors each having a capacity of 225 tons, the cylinders being 18½ in. diameter x 46 in. stroke. Both compressors were supplied by the Linde British Refrigeration Co., Ltd., Montreal, and are each direct connected to a Leonard Corliss engine, having a cylinder 22 in., diameter x 42 in., stroke and running at 60 r.p.m. The flywheel of each unit weighs 25,000 pounds and is 14 ft. diameter with a 12 in., face. The engines are equipped with safety stops and "Bowser" automatic journal lubrication, the oil being supplied by means of a small pump. The compressors have double suctions, the front end being connected to the ice tank, air cooler and piping in the abattoir building for Oleo cooling and storage. The back end of the compressors is connected to the sharp freezers on the third and fourth floors of the cold storage building, and the double pipe brine cooler in the basement of the same building.

The ammonia condensers are located on the roof over the ice tank room, and are of the "Wolfe" patent atmospheric type. They consist of 16 sections of 2 in. diameter pipe, 24 pipes high, fitted with a galvanized water trough over each coil and complete with all necessary gas and liquid headers and pump out connections. The liquid receiver which is placed below the condenser on the top of the engine room roof is 24 in., diameter by 16 ft., long with stands and valves. Water from the city mains circulates over the condensers and down to a tank on the boiler room level.

Ice Tank.

The ice plant has a capacity of 30 tons of opaque ice per day and is situated in a building alongside the engine room. The plant is operated on the flooded system and consists of a steel tank 56 ft. 9 in. x 21 ft. 9 in. x 48 in. deep and is made of 1/4 in., plate. The tank is divided into two sections, containing 416 cans of 300 pounds each; the cans measuring 11½ x 22½ x 44 in. deep inside. The tank is equipped with 8,000 ft., of 1¼ in. extra heavy coils placed in racks between the cans and connected to a liquid accumulator 24 in., diameter x 5 ft., long, from which the gas is drawn back to the compressor.

The brine in the tanks is circulated by means of two propellers 18 in., diameter running at 160 r.p.m., and driven by a 5 h.p. C.G.E. motor. Over the top of the tank there is an air-operated traveling crane operating over the full length of the room and having a capacity of 750 pounds, which is equivalent to lifting two cans at one time. The crane is equipped with a "Curtis" air hoist, the air being furnished by a Canadian Westinghouse, railroad type, compressor located in the engine room. The cans are carried to the thawing tank containing warm water which loosens the ice. The ice is then placed in the dump and delivered to a platform outside where it is carried by an elevator to a crusher and then delivered to the refrigerator cars. The tank is insulated in the bottom by cork board 6 in. thick and the sides are formed by the building having hollow walls with a 12 in. space filled with granulated cork.

Cold Storage Building.

The cold storage building on the east side of the property is constructed of reinforced concrete with brick "curtain" walls, concrete columns and floors. There are four floors, basement, and sub-basement, each having a cubic capacity of 95,000 feet. The fourth or top floor contains the sharp freezers. Part of the third floor is taken up by the offal freezer, the other part being a cool room, while the other floors and basements are cool rooms.

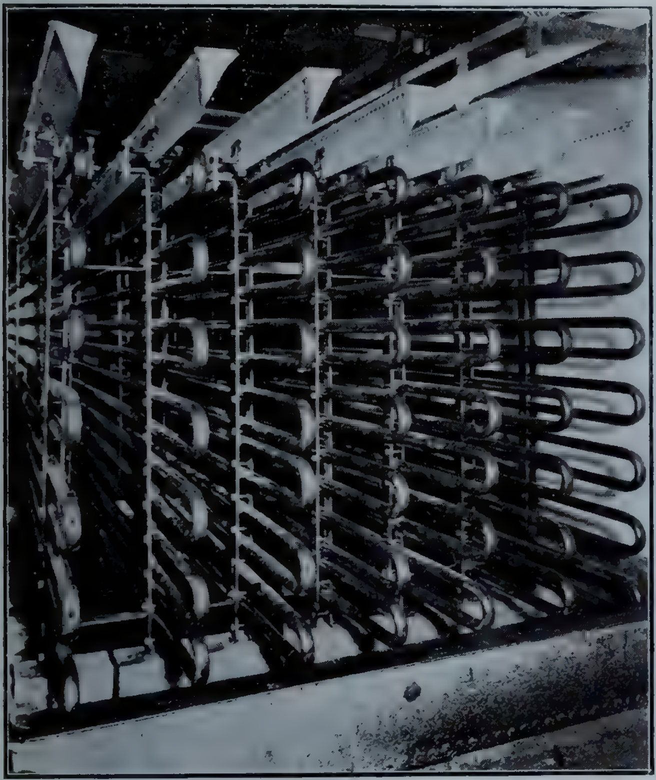
The top floor is divided into three sharp freezers, maintained at zero by a total of 18,000 feet of 2 in. direct expansion piping placed in grids suspended from the ceiling. The offal freezer on the third floor is cooled by piping placed in a similar manner and has also four pan freezer coils made up of grids of 2 in. piping placed in 16 in. centres and connected at one end by headers to the liquid and suction lines. The other section of the third floor is used as a hot beef cool room and is cooled by an air circulating system from coolers in the basement. The second and first floors are beef rooms while the basement and sub-basement are cutting and pickling rooms respectively. All the cool rooms are cooled by the air circulating system from air coolers located in the basement. The rooms are held at a temperature of from 30-32 degrees F.; each has a cubic capacity of 95,000 feet.

Air Coolers.

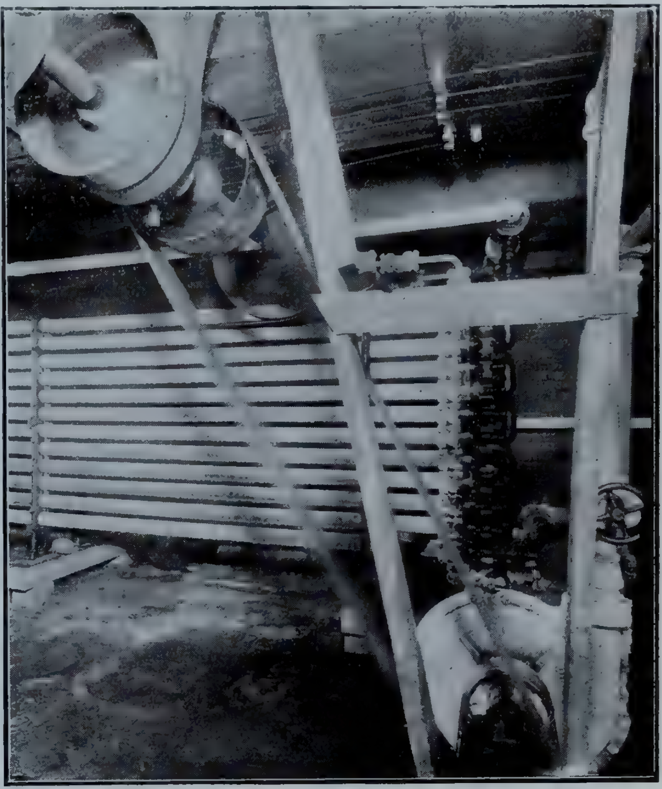
In the basement there are four air coolers arranged in separate units, each consisting of 3,000 feet of 1¼ in. extra heavy piping made up in grids and placed over a shallow tank for containing the brine, which is pumped from the brine cooler by a 2½ in. Smart-Turner centrifugal pump, located in the fan room adjoining. Galvanized iron troughs are laid over the full length of each coil for distributing the brine equally, thereby preventing frost from forming. The brine is cooled in a double pipe brine cooler, located in the fan room, and containing 725 feet of pipe. The inside or brine pipe is 2 in. diameter and the outside or ammonia pipe is 3 in. diameter.

There is a Sturtevant, multivalve type, fan installed with each cooler which draws air through the latter and delivers it through ducts to the cool room with which it is connected. The ducts are so arranged that the coolers can be operated together or as separate units. The fan and brine pump are driven by a 25 h.p. C.G.E. motor.

Outside the fan room is a closed brine tank and pump installed in connection with the lard roll on the first floor. The brine is cooled in the brine cooler already described. The centrifugal pump has a capacity of 100 U.S. gallons per minute against a head of 92 feet and is direct connected to a 5 h.p. motor running at 1,500 r.p.m. The pump and



A COOLER SHOWING AMMONIA COILS AND BRINE TANK.

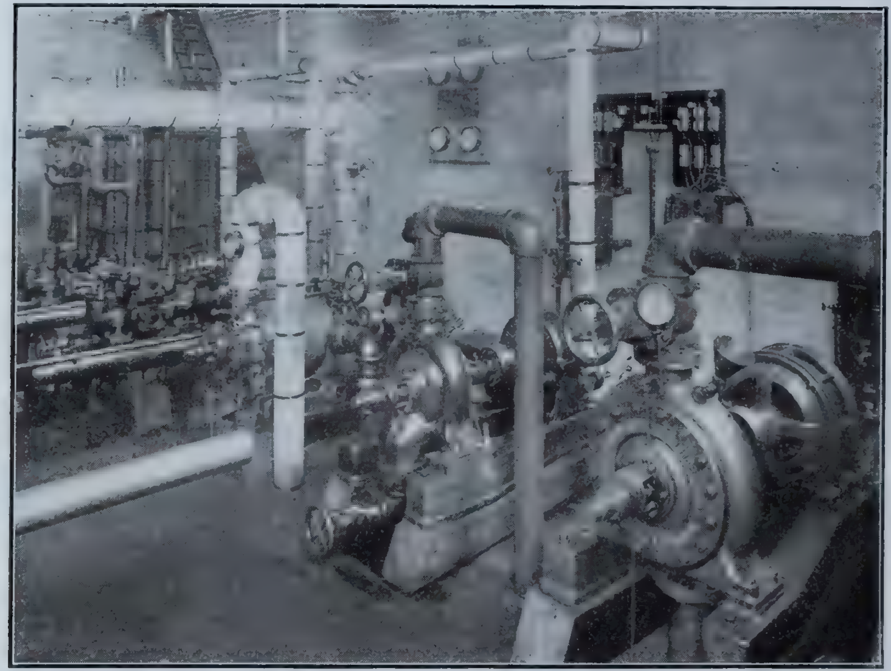


DOUBLE PIPE BRINE COOLER AND BRINE PUMP.

motor were both supplied by the Canadian Allis-Chalmers Co., Toronto.

The building is constructed with hollow walls having a 10 in. space filled with granulated cork, which forms the insulation for walls of the cool rooms and sharp freezers. The floor of the sharp freezers is laid with 4 in. cork board, and the roof is covered with 6 in., cork board over which is laid 4 ply standard roofing material. The floors and ceiling of the cool rooms are not insulated, but the walls of the coolers are insulated with 4 in. cork board. The insulation throughout the plant was supplied by the Kent Co., Montreal.

In the abattoir building there are three coils in the fat cooling vats and there are also coils in one room on the ground floor which is used as a storage for oleo.



BOILER FEED AND SERVICE PUMPS.

General Features.

In the abattoir building a machine shop has been equipped for making general repairs to the electrical and mechanical equipment. The machinery installed includes pipe threading machines, drill presses, lathes, etc.

The cold storage and the abattoir building are connected by a tunnel on the sub-basement level for providing a passage-way and also for carrying all the ammonia and steam piping and electrical wiring from the power house to the cold storage building and also to the office building.

The plant went into operation on November 1, 1913, and Mr. George Imrie, the chief engineer, advised our representative that the mechanical equipment throughout had given perfect satisfaction. The boiler installation had worked without a hitch and the pumps, engines and ammonia compressors had been thoroughly reliable.

◆

THREE-STRAND VERSUS FOUR-STRAND TRANSMISSION ROPE.

ALTHOUGH a large amount of four-strand transmission rope is used on the American continent, a three-strand rope is generally preferred in Great Britain and throughout Europe. It is in many respects the better of the two. Three-strand rope is laid more closely, and, there being no heart or core, the strands bear evenly on one another. With a four-strand rope, on the contrary, there is a space left in the centre which is usually filled up by a core.

The rule generally adopted in calculating the number of yarns which the core should contain is: Divide the number of yarns in all the strands composing the rope by 13. Take the case of a four-strand rope containing 132 threads—the core would be equivalent in bulk to 10 threads, while each of the strands would contain 33 threads. It will thus be seen that the core is much inferior in strength to any single strand, the result being that when the rope is strained the core is the first part to give way. Once the core is broken a space is left in the interior of the rope, one of the strands cuts in, the rope is stranded, and after a time goes to pieces.

Moreover, the strength of a four-strand rope is considerably less than that of a three-strand rope of the same diameter. A number of tests carried out by the United States Government at the Watertown Arsenal gave the following results:

Circ. Size.	3-strand.	4-strand.
2¼ inch.	6,206 lbs.	4,633 lbs.
3 inch.	9,800 lbs.	8,583 lbs.
4½ inch.	20,873 lbs.	18,100 lbs.

The above figures give the average of three tests on each size of rope, the ropes being pure Manilla. In addition to being stronger, three-strand rope can also be more easily and thoroughly spliced than four-strand, but the latter has the advantage of stretching less and also gives a larger surface in contact with the grooves in the pulleys.

◆

TORONTO HYDRO-ELECTRIC SYSTEM.

LAST year's business brought a net surplus of $34,576 into the coffers of the Toronto Hydro-Electric System, or approximately 3 per cent. on the total investment. The gross income amounted to $1,159,339.71 for the year, while the cost of current and the expenses of operation and management, including repairs and maintenance, absorbed $681,217.01, leaving a net balance of $478,122.70. The interest, depreciation, and sinking funds for the year amounted to $443,546.83. These figures show that the operating expenses were reduced 5½ per cent. from those of 1912, and the cost of current lower by 4 2-3 per cent., chiefly due to the reduced charge made by the Provincial Commission.

Notwithstanding the request of the Provincial Hydro Commission in regard to the reduction of rate, the report of the commission issued recently declares that a reduction of rates at this period in the development of the system would be unjustifiable. The statement points out that no complaint has been received from the customers relevant to the rates, but the commissioners state that whenever conditions warrant it, a reduction will be made, and say that it would be a breach of trust on the part of themselves to sanction any reduction before the financial condition of the enterprise justified it. "It is the policy of the commission to give in the first place a first-class service," reads the report, "and in the second place to give that service at the lowest cost possible. That policy will be strictly adhered to."

◆

Woman Wants Engineers' License.—Mrs. Victor Garnish, who was for twenty years a licensed engineer in Minnesota, on April 4, applied to take out a license in Regina to run her husband's traction engine, but the Saskatchewan law allows male engineers only. She says there are many women in the Province who would become engineers if they could.

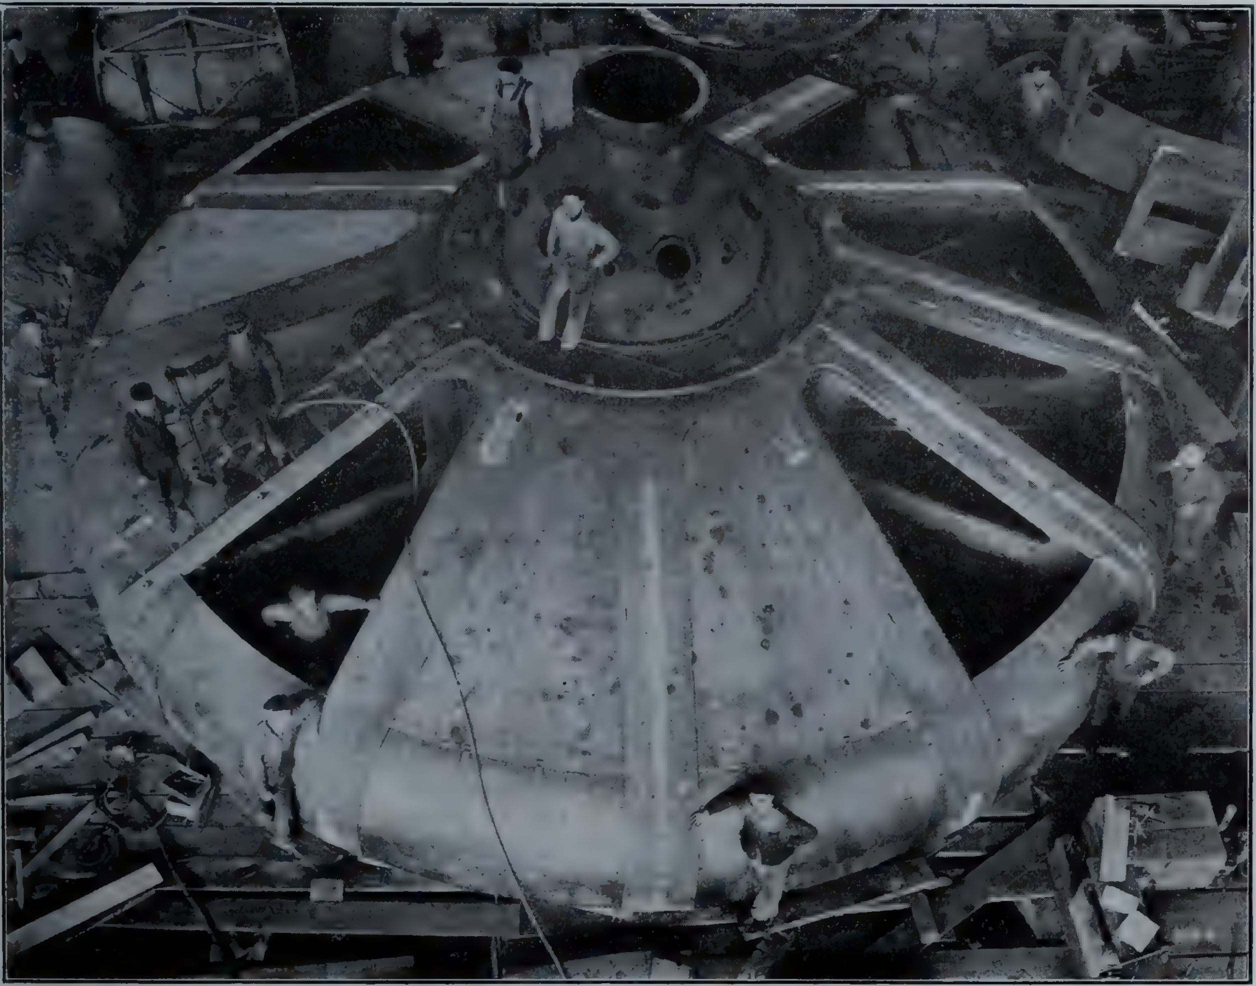
The Design and Construction of Hydraulic Turbines[*]

By H. B. Taylor, M. Am. Soc. M,.E.[**]

The development of the water powers of the world has turned the inventive genius of men in the direction of machine design distinct from that akin to steam operation, and the achievement realized in the latter sphere is being to a large extent duplicated in the production of engines whose motive power is derived from the harnessing of waterfalls in this and many other countries where the particular natural resources are available.

DURING the past ten years, hydraulic turbine design has passed through a stage of wonderful development and, in respect to many features, remarkable progress has been made toward bringing the turbine to a high state of perfection.

1. As a result of theoretical investigation, substantiated by experimental research of the highest order, efficiencies have been increased on the average about 10%.



MAIN UNIT THRUST BEARING SUPPORT, 10,800 H.P. VERTICAL SHAFT SINGLE RUNNER TURBINE FOR THE CEDAR RAPIDS MFG. & POWER CO., MONTREAL, UNDER CONSTRUCTION IN THE SHOPS OF THE I. P. MORRIS CO., PHILADELPHIA.

2. Corrosion of runner vanes, at one time a serious factor as affecting the maintenance of turbines and their efficiencies, has been eliminated subequent to conclusive demonstration that it is primarily the result of defective design.

3. The development of high specific speed runners, thereby permitting the use of higher rotational speeds, has resulted in the rapid passing away during the past few years of the multi-runner types of turbines in favor of the vertical shaft, single runner type.

4. At one time it was generally thought that the character of speed regulation of a turbine was dependent entirely upon the governor. To-day, however, it is known that the make or type of governor has little or nothing to do with speed regulation, except in so far as it must have sufficient power and proper mechanical adjustments to move the turbine gates in a certain time and without hunting.

Efficiency.

Ten years ago it was considered a notable achievement to obtain from a turbine in place an efficiency as high as 82%. The average of the best results secured was in the neighborhood of 80%. The maximum guarantees of the builders were from 78% to 80%, and were considered highly satisfactory. During the past two years, efficiences between 89% and 92% have been quite common, while a maximum value of 93.7% has been secured. To-day the builder must guarantee an efficiency of at least 87% in order to secure business.

---

[*] From paper read before the Mechanical Section of the Canadian Society of Civil Engineers, Montreal, on Jan. 15, 1914.

[**] Hydraulic Engineer, the J. P. Morris Co., Philadelphia.

This remarkable increase in efficiency is by no means entirely due to superior runner design. As a matter of fact, the improvements in the design of wheel-casings, wicket gates, draft chests and draft tubes have increased the efficiency of the turbine as much as the more efficient runners.

It is interesting to note that the improvement in turbine efficiency has taken place during the time when the general policy of the power companies toward the builders has changed from one under which a great majority of contracts were awarded to the lowest bidder to the present one under which merit is frequently given first consideration. Under the former policy, business was secured by the builders at such prices as to allow little or no margin between actual cost and selling price. As a majority of turbine installations undertaken ten years ago were unsuccessful at the start, and required alterations or replacements to make them acceptable, the contracts which showed a profit were few and far between. Thus, there were frequently no funds available to cover the cost of experimental work by the builder to improve the quality of his product. As the data available ten years ago was by no means reliable, a majority of the buliders had very little assurance of the successful outcome of their work. There was, consequently, a very strong incentive on the part of some of the builders to avoid, if possible, the making of any tests which might prove that the apparatus had failed to meet the guarantees.

Merit of Product the Factor.

Most of the important contracts are now awarded on a basis of merit, and designs and guarantees are given far more consideration than price. A great amount of work is done on a cost and percentage basis, whereby the builder is guaranteed a profit, contingent, of course, on the proper execution of his part of the agreement. The ability of the builder properly to construct the apparatus in accordance with his designs is now taken into consideration in comparing competitive designs. A high guarantee of efficiency is no longer satisfactory to the purchaser unless it can be justified by conclusive evidence in the form of reliable data secured from tests on similar apparatus, or in connection with experimental turbines tested by disinterested parties. The builder who, by the presentation of such data, demonstrates that his guarantees will probably be exceeded, is given preference over his competitor who, although he may have made the same guarantees, is unable to prove that he has an equal margin in reserve.

Power Company Co-operation.

Engineers of power companies are now taking a much greater interest in the experimental work of the builders than previously, frequently volunteering to share in the expense; provided, of course, that such work will be of some aid to them in selecting the best type of apparatus. In some instances, power companies have allowed under contracts certain sums of money to be expended on experimental work to be carried out by the builder. In many contracts for waterwheels placed during the last few years the builders have been required to guarantee the efficiency on a bonus and penalty basis, the rate ranging anywhere from $1,000 to $5,000 per unit for each one per cent. of efficiency, the rate in each particular case depending, of course, upon the value of efficiency to the purchaser. This co-operation on the part of the power companies has been a very important factor in producing the remarkable improvement in efficiency which has been obtained during the past ten years, for it has made possible the expenditure by the builders of very considerable sums of money to cover the costs of research and experimentation. There is probably no doubt in the mind of anyone that the power companies have benefited many times more than the builders as a result of the experimentation made possible by their liberality. Another important factor in the rapid strides made in waterwheel design during the past ten years has been the co-operation on the part of consulting hydraulic engineers who, necessarily, have had a very extended and valuable experience in the design and operation of hydraulic machinery, and in the efforts of builders to solve various problems which present themselves, the advice of these engineers has been eagerly sought and cheerfully given.

Turbine Performance a Primary Consideration.

The present atitude of the power companies toward the builders has undoubtedly been the result of a better appreciation of the fact that the success or failure of any hydro-electric development depends primarily upon the performance of the turbines. The total investment of a hydro-electric development is represented in the water rights and franchises, the dam and power house, the turbines, generators, electrical transformers, the transmission lines and other equipment. This investment may involve many millions of dollars. The amount paid for the turbines themselves is only a small proportion of the total investment—say from 2½ to 10%. When it is considered that the success of the total development is absolutely dependent upon the proper performance of the turbines, and that the earning power of the total investment may be in proportion to the efficiency of the turbines, the folly of chancing the installation of inferior apparatus is self-evident.

In comparing designs prepared ten years ago with recent designs, the most striking feature is the absence in the latter of sudden turns and abrupt changes of section in all water passages from the turbine casing to the tail race; and, although in the older designs these passages were thought to be consistent with good results, they now appear to be exceedingly crude. The elimination of losses due to eddies and whirls, abrupt changes of section and sudden curvature in the various parts which constitute the turbine has improved the efficiency of the turbine as a whole. By means of the Pitot tube, it has been possible accurately to determine the conditions of flow in the various parts of the turbine casing, through the guide vanes, in the space between the guide vanes and the runner, and also in various sections of the draft tube. Thus it has been possible to compare actual conditions of flow in these various parts with the calculations.

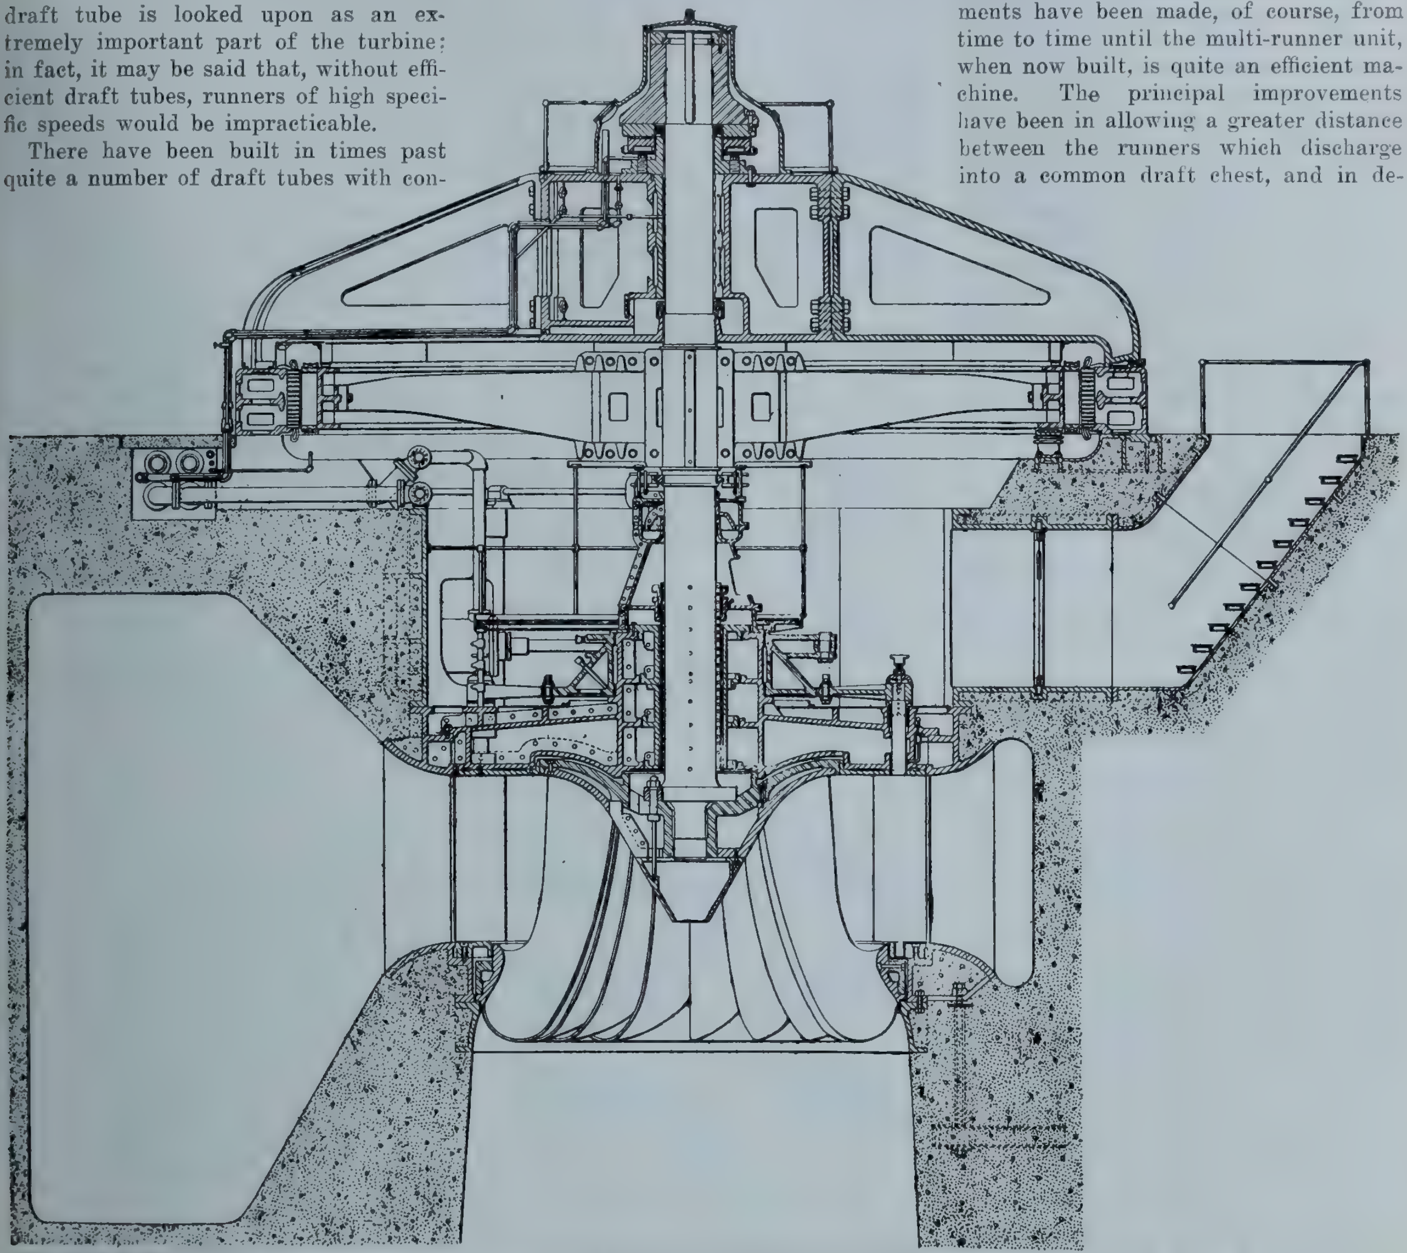
Waterwheel builders in the past five years have carried on very extensive tests at the Holyoke testing flume in Massachusetts on small runners ranging, in most cases, from 12 to 30 inches in diameter. These runners are exact models of the large runners which the builders contemplated installing in the turbines. Various designs of wicket gates and draft tubes are used in connection with the testing of these models. The results of these tests have given the builders very valuable data upon which to base the design of any new work calling for runners of like characteristics. The builders have also been able to secure from these tests empirical constants by which they have been enabled to modify their theoretical data.

Draft Tube Feature.

The head corresponding to the velocity of discharge from the runner into the draft chest or tube may represent a considerable proportion of the total head acting on the turbine. This is especially true in the case of runners of high specific speed, where this velocity head may be as great as from 25% to 30% of the total head acting on the turbine. It is, therefore, essential to design the draft tube most carefully, in order to convert this velocity into effective head.

Improvement in the design of draft tubes has been very marked indeed and has resulted in a considerable increase in the efficiency of turbines. It has only been within recent years that the hydraulic conditions within the draft tube have been fully appreciated. It was at one time thought that the draft tube was simply a device by means of which it was possible to locate the turbine above tailwater level without losing the effective head represented by the difference in elevation between the turbine and the tail race. To-day, however, the draft tube is looked upon as an extremely important part of the turbine: in fact, it may be said that, without efficient draft tubes, runners of high specific speeds would be impracticable.

There have been built in times past quite a number of draft tubes with constant diameter from the rummer to the tail race. Consequently, the velocity which existed in the section immediately at the discharge from the runner existed also at the end of the draft tube, and the energy represented by this velocity was entirely lost to the turbine, in addition to the frictional loss resulting from the condition of high velocity throughout the entire length of the draft tube. The efficiency of turbines with draft tubes so designed is necessarly extremely low. By properly designing the draft tube from the section immediately at the discharge from the runner to the tail race so that the velocity is gradually reduced from a maximum at the runner to a minimum at the tail race, the vacuum in the draft tube may be increased and, consequently, the effective head on the turbine.



CROSS SECTION OF A 10,800 H.P. VERTICAL SHAFT SINGLE RUNNER TURBINE UNIT FOR THE CEDAR RAPIDS MFG. AND POWER CO., MONTREAL.

The Runner Feature.

Until the last two years, a large majority of the turbines installed in connection with low and medium heads were of the old fashioned multi-runner type, consisting of two, four, six and sometimes more runners on a shaft, these runners being grouped in pairs, each pair discharging into a common draft chest and tube. The energy represented by the velocity at the discharge from the runners was practically lost to these turbines, owing to the losses due to impact and eddies and whirls existing in the draft chests and tubes, as a result of the runners discharging against each other. Consequently, there was practically no reconversion of the velocity head from the runners into useful head.

Ten years ago, the draft chest and draft tube designs of turbines of these types were exceedingly crude. Improvements have been made, of course, from time to time until the multi-runner unit, when now built, is quite an efficient machine. The principal improvements have been in allowing a greater distance between the runners which discharge into a common draft chest, and in designing the draft chest so that the water from each runner is carried into the draft tube to a point where the two streams are moving in parallel directions, before allowing them to converge; but even with the best design of turbines of the multi-runner type, there is always present an appreciable loss due to the comparatively sudden turns which the discharge water from the runners must necessarily follow.

With runners of medium specific

speed in a multi-runner setting, it is sometimes possible to obtain efficiencies approaching those developed by the experimental runner; provided, of course, that the draft chests and draft tubes have been carefully designed. In other words, the losses in the draft chest and draft tube about equal the losses which exist at the Holyoke testing flume, where the runner is small, and where the intake and draft tube losses are necessarily appreciable on account of the construction of the flume. On the other hand, should runners of extremely high specific speed be adopted, in which the discharge velocity from the runners represents a very considerable portion of the total head acting on the turbine, it is found that the efficiency seldom reaches that of the experimental model. It may be mentioned that the experimental model is usually operated in a vertical setting, with a single draft tube, and consequently the losses which exist in the draft chest of the multi-runner setting are not present in the experimental setting.

Reliability and Stability of Construction

In many of the power developments carried out a number of years ago, and in some few instances in more modern plants, even such efficiency as could be obtained from the turbines cannot be realized in the operation of the plant as a whole. Poor designs of the waterways leading to the turbine casing and receiving the discharge from the draft tube cause considerable losses outside of the turbine passages. In some instances, much attention has been given to slight variations in turbine efficiency, while losses of head amounting sometimes to one or two feet, occurring through submerged arches, bridge piers or racks, have been overlooked.

Many recent developments are being much more carefully worked out, so that there are gradual transitions in water velocity at entrance to the turbine casing and at discharge from the draft tube into the tailrace; and practically the entire efficiency of the turbine is realized in the operation of the complete plant.

Accompanying a growing appreciation of the value of efficiency, engineers are giving increased attention to the mechanical features of turbine designs and to questions of deterioration of the machinery during operation. It is now realized, especially by those who have been taught by the school of bitter experience, that mechanical reliability and stability of construction are of even more importance than efficiency, since continuity of operation and freedom from interruption for repairs are vital considerations. Among other sources of interruption to service, the deterioration of runner vanes has in the past been a frequent cause of trouble.

Corrosion of Runner Vanes.

Corrosion, or pitting, of runner vanes, guide vanes and draft tubes, is no longer a serious obstacle to be contended with in the operation of hydraulic turbines as its cause is now pretty well understood and, by correct designing, can be eliminated. Turbine builders do not hesitate to design and construct turbines for operation under any head up to 650 feet and to guarantee their lasting qualities, provided the speed and power in each case are so chosen as to be consistent with favorable hydraulic conditions. Corrosion, or pitting, must be distinguished from erosion, which is mechanical wear due to the presence of foreign substances in the water. Erosion is entirely a mechanical action, while corrosion, or pitting, is the result of chemical action. The abrasive action of foreign substances in the water has the effect of first polishing the vane surfaces, and eventually cutting away the metal until the vanes are worn entirely through. The eroded parts are, therefore, smooth and can be readily distinguished from the pitted marks which result from corrosion.

The elimination of corrosion as a serious factor in turbine design is the result of a careful study of the subject, after many years of costly experience on the part of both the power companies and the turbine builders. It has been demonstrated that corrosion is primarily a question of design. It has been clearly shown in practice that where sharp curves are resorted to, where contraction is not sufficient, or where there are pockets formed in the surface of the vanes, pitting or corrosion inevitably develops. It has also been demonstrated that where air in large quantities is entrained in the water carried to the turbine, corrosion seems to take place very rapidly if the design is not correct.

While it is true that corrosion takes place more quickly under high heads than under low heads, runners operating under heads as low as 25 to 30 feet have been found in some cases to corrode very rapidly. It is, therefore, essential that the runner be carefully designed, regardless of the head under which it is to operate, but extreme precaution must be taken in cases where the head is excessively high. A corroded vane surface has an appearance resembling a sponge, the surface being extremely irregular and the pitted spots often opening holes entirely through the vane. Chemical analysis of the corroded surfaces has brought out the fact that the metal has been oxidized. In runners made of bronze or an alloy, modifications in the composition have been detected in the corroded portions.

Theory of Corrosion.

The theory of corrosion as now generally accepted is that the water in passing over any pocket or depressed surface, or in failing to adhere to the surface of the vane, leaves spaces which are filled with eddies possessing high velocities and very low static pressure, in which oxygen is liberated from the water. This oxygen is believed to be in the nascent state and rapidly attacks the surface of the metal, forming an oxide coating, the greater part of which is rapidly washed away by the water. When once the depth of this pocket is increased by corrosion, it is natural that, due to the greater area exposed, the pitting action should continue at an accelerated rate until the vane is entirely eaten through.

It is quite likely that electrolysis is present as a result of the oxidation of the metal, for it has been noticed in connection with runners of the built-up type—viz., runners in which plate steel vanes have been used with iron or bronze bands and hubs—that corrosion seems to develop more rapidly than in the case of runners made of uniform metal. Foreign engineers have called attention to the fact that in some instances they have observed that the metal eaten out by corrosion at one section of the runner has apparently been re-deposited at another section, a condition evidently resulting from electrolysis. If electrolysis does exist, it is a secondary action and may be eliminated by first preventing corrosion.

The fact that a runner develops high efficiency under test is not, necessarily, a guarantee that corrosion will not take place. Small defects in the curved surfaces of the runner vanes will be very quickly brought out by the fact that they corrode; while on the other hand these defects in the flow through the runner, may be too small to be detected in an efficiency test. In general, however, it may be said that high efficiency and freedom from corrosion are complementary qualities.

* * *

Vancouver, B.C.—A new cold storage plant is to be erected by the Vancouver-Prince Rupert Meat Co. on Water Street, at a cost of about $80,000. A building permit was taken out in January for the basement portion, costing $6,000, and since then plans have been in preparation by the company's architect. The building will be 33 feet by 120 feet and six storeys in height. It will be of brick and mill construction and complete as regards facilities for handling meat for Vancouver consumers.

Breakdowns of Stationary Engines, Their Cause and Cure-II.

By Michael Longridge

The accompanying article, which formed the subject of a recent lecture before the Graduates' Association of the Institution of Mechanical Engineers, is one of special interest to power plant operatives. While this is so, the fact that faulty design and careless installation have played a large part in many "smash-ups," makes the advice relative thereto of considerable value to those whose work lies in these particular spheres. The author of the paper is the well-known Chief Engineer of a large and leading English power plant equipment insurance company.

IN our March issue the contributory part that flywheels, valves and valve gears, pumps, bed-plates and cylinders, played in the matter of stationary engine breakdowns was discussed. In the present and succeeding article on the subject the relative place which spur gears occupy is dealt with.

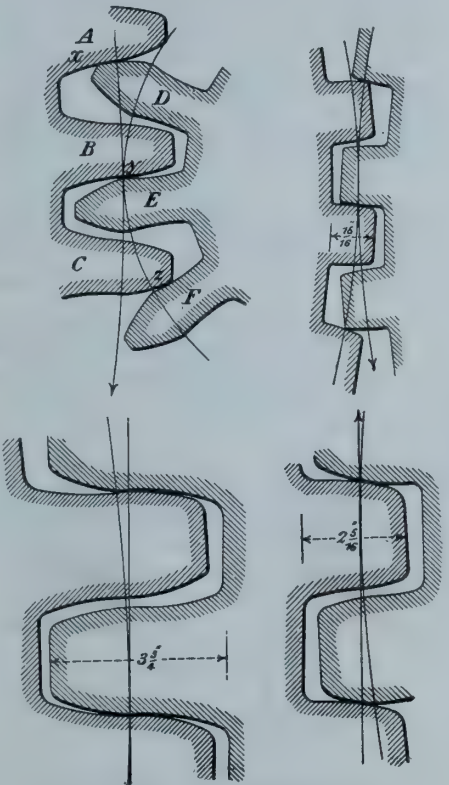
Spur Gearing.

About 1879, when horizontal engines of 800 to 1,200 indicated horse-power began to replace beam-engines of half that power in cotton mills, when pitch-line speeds were rising from 1,800 ft. to 2,300 ft. per minute, loads on teeth from 10,000 lbs. to 18,000 lbs., and gear ratios from 2¼ to 1, 3 or 3½ to 1, an epidemic of breakages of spur-gears set in. Some 20 per cent. of the engine breakdowns were breakages of spur-wheels on engine crank-shafts, and the pinions driven by these wheels broke almost as frequently. Many of these breakdowns were due to irregularities of pitch, twisted teeth, sinuosities of pitch circles, concentration of pressure on the end of teeth through movement of crank-shaft, back-lash from the momentum of rope-drums on second-motion shafts, and other faults of workmanship and use, common to old-pattern moulded wheels and to old engines.

The damage, however, was not confined to these. Many new wheels, as good as mechanical skill could make them, with teeth moulded by machinery, spur-runs, cast in complete circles, and machined internally, carried on crank-shafts held in pedestals, with brasses adjustable horizontally as well as vertically, broke also. These breakages were usually attributed to "vibration," "wear and tear," "teeth bearing up to points," and similar effects of a cause ignored or not discerned. That cause, in my opinion, was the use of teeth too long and too wide to "correspond with their environment," the most important fact of that "environment" being the unavoidable motion of the engine crank-shafts on which the driving-wheels were hung.

Spur Gear Breakage Explanation.

I will try with the aid of Figs. 32 to 35 to make this clear. Fig. 32 represents three teeth (A), (B), (C), of a spur-wheel geared with three teeth, (D), (E), (F) of a pinion. The teeth are supposed to be cycloidal, for involute teeth have not found favor with makers of main driving-gear. Their length is exaggerated to make this illustration clear. Similar profiles can be set out, according to the rules in the books to provide three points of contact (x), (y), (z), and three teeth to carry the load. They look very pretty upon paper, but they will not work if the spur-wheel (A), (B), (C) be forced towards the pinion (D), (E), (F), by the motion of the shaft.



FIGS. 32, 35. SPUR GEAR TEETH BREAKAGE FEATURES.

The contact at (y) ceases. The pressure is taken off (B) and is concentrated upon the points of the teeth (C) and (D), and there intensified enormously by the forcible retardation of the driving-wheel or acceleration of the pinion. Again, even if the crank-shaft could be held absolutely steady, the same effect might be produced if the teeth came from the mould full at the points, or if the pitch-line had proud places, both common defects in uncut wheels. If, however, the faces of the teeth were cut away sufficiently to limit the contact to the immediate neighborhood of the pitch-point (y), the motion of the wheel towards the pinion would simply cause the tooth (B) to slide on (E) without strain or change of angular velocity.

Of all intermediate positions of the point of contact it may be said that the further it moves from the pitch-point, the more destructive become the effects of shaft displacements, incorrect tooth forms, or sinuosities of pitch lines, and conversely the shorter the path of contact the less the mischief resulting from these unavoidable irregularities. Experience has led millwrights to the same conclusion, for they invariably set out wheel teeth so fine at the points and roots that they bear only near the pitch line when new, and when through wear the bright bearing surfaces extend to the points of the teeth, they chip the points to avert the damage just referred to.

The question is, why do they leave surfaces which are not used when the teeth are new and which have to be chipped off when the teeth are old To this I never could get a satisfactory answer. Neither as far as I know, would wheel makers cut short their teeth till 1888, when a firm of engineers consented to make a pair of wheels with short teeth, Fig. 33, for their own shop engine.

These wheels must have felt like the first lady who appeared in public minus a crinoline, so greatly did they differ from the fashion of their day. They had 49 and 47 teeth, of 2 5-8 in. pitch, 15-16 in. long and 4 1-2 in. wide, the ratio length to pitch being 0.36. With fixed centres and accurate moulding, teeth 1-4 in. long would have kept contact. These wheels held their grease well and ran smoothly, till the engine was replaced in 1892. They were but small, and running at a low speed (1080 ft. per minute), but they were more convincing than arguments or drawings, because they were made of cast iron and could be seen at work.

Figs 34 and 35 show what they accomplished in a few months. The former shows the teeth of a wheel and pinion installed in November, 1888, after two other sets of gearing had been destroyed in the space of eleven years. The teeth were 4 13-16 in. pitch, 3¾ in. long, and 19 in. wide, while the distance between the centres of the shaft-bearings was only 66½ in. With these dimensions and a pitch-line speed of 2410 ft. per minute, the motion of the crank-shaft threw the whole load of 16,400 lbs. upon the corners of the teeth and drove the points of the pinion-teeth into the flanks of the wheel-teeth with jar and vibration sufficient to break one of the segments in the following March. Then more teeth were cracked and more segments broken, and it became necessary to replace the entire rim. The new rim was made of steel, with teeth of the same pitch and breadth as the old, but 2 5-16 in. instead of 2¾ in. long, Fig. 35. They would have been better 1½ in. long.

The tooth of an engine-driving-wheel is a cantilever whose strength varies not as pitch 2 × width ÷ length, but as pitch ÷ length, because, with a short and moving crank-shaft, very little, if any strength is gained by making the width of a tooth more than one pitch. Thus a reduction of length to 1½ in. would have permitted a reduction of pitch to 3¼ in., an increase in the number of teeth in both wheels, a shortening of the necessary path of contact, and, if three pitches be considered a sufficient width for the teeth of one engine driving-wheel, as I think it is, less concentration of pressure on the corners from the lifting of the shaft.

Double Helical vs. Straight Teeth.

Some people consider double-helical teeth stronger than straight teeth. This is a delusion. Width for width of wheel-face, they are much weaker, because, owing to the lifting and end-long motion of crank-shafts, the pressure never acts on both treads at the same time, unless provision be made for allowing the pinion-shaft to move end-ways, and, even, then, the force required to overcome the inertia of the pinion and its shaft adds seriously to the pressure on the teeth. There is another cause of destructive vibration—namely, irregularity of pitch and inequality of pitch of wheel and pinion. The first is seldom important in machine-moulded wheels, and can generally be rendered innocuous by chipping and filing. The second, depending upon the contraction of the castings, can only be remedied by gearing the wheels more or less deeper than was intended by the designer.

In my opinion, both wheels of a pair should have pitch circles turned on both sides of the rims, with radii proportional to the number of teeth in each, whether they be the radii marked on the drawing or not. The wheels should be geared to these circles and kept there. The change of the position of the pitch-point on the profile will not materially affect the velocity ratio if the teeth be short. The fashionable length of teeth is now 0.45 to 0.55 of the pitch, instead of 0.66 to 0.75 as formerly, and it might be reduced still more with advantage in many cases.

I should like to have said something about the breakages of spur-wheels other than breakages of teeth, but as most of the breakdowns of these wheels originate in the teeth, it seemed best to devote the time available exclusively to them. The breakages of spur-gearings are now 10 per cent. of the total breakdowns. The reduction in the percentage from 20 to 10 is principally due to the supersession of gearing by ropes. The improvements in design and workmanship have done little more than enable wheels to live under conditions which the old wheels could not have faced, but they have done something, and the substitution of steel for iron, of cut or milled for moulded teeth, and of shorter teeth and correspondingly finer pitches, will do a little more, but I doubt if it will ever be possible to transmit more than, say, 1200 horse-power from the crank-shaft of a steam-engine by spur-gearing.

FACTORY ACT AMENDMENTS.

INSPECTION of all boilers in use in Ontario, excepting those in private residences, is to be made compulsory in an amendment to the Factory Act introduced into the Legislature by Hon. James S. Duff last week. The present law provides for the inspection of all boilers used in factories, shops and office buildings at least once a year, but there appears to have been no inspection of boilers in hotels, schools, theatres and other public buildings.

The proposition for general inspection was first linked with the suggestion that the boilers be inspected by the province, but as half the boilers in the province are under private inspection, the boiler insurance companies would practically be forced out of business.

The Stationary Engineers Act is to be amended, bringing all men in charge of hoisting engines under the law, so that in future they will have to secure certificates as other stationary engineers have to do.

The Rope Drive as a Power Transmission Medium

By E. H. Ahara, Mishawaka, Ind.

Being an abstract from a paper read before the American Society of Mechanical Engineers, covering a series of tests on the transmission of power by rope-drive under various conditions.

CONCLUSIONS deducible from the data obtained seem to show that the efficiency in rope driving is considerably greater at the lower speeds than at the higher ones, the dropping off being especially noticeable above 4,500 ft. per min. of rope speed. They also show that the efficiency of a rope drive is not materially affected by distances between centres up to 150 ft., that the drop of

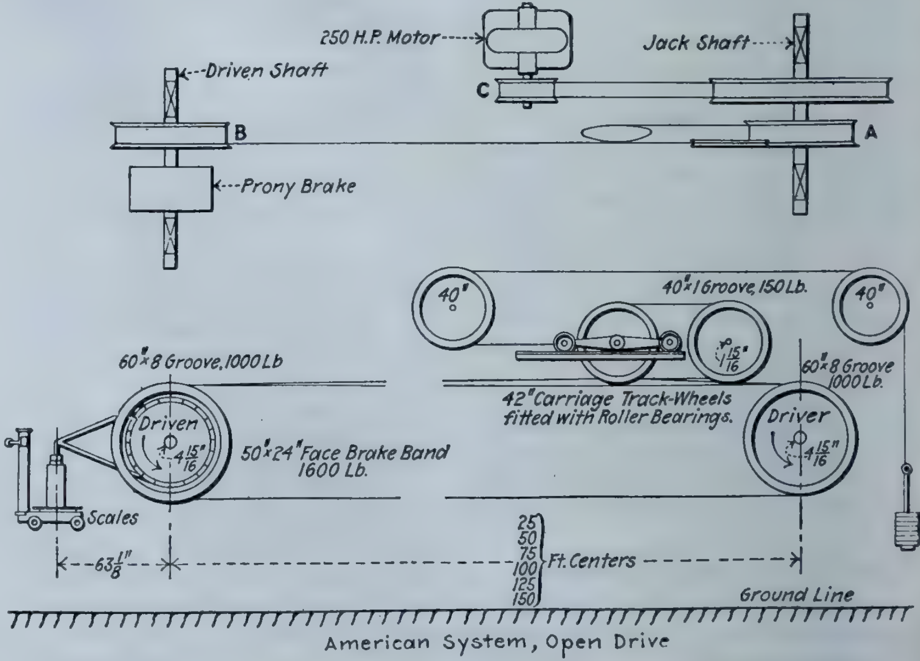


FIG. 1. GENERAL PLAN OF AMERICAN OPEN OR STRAIGHT DRIVE SYSTEM.

efficiency at 50 per cent. load is comparatively small over that of full load, and that if proper care be exercised to have all grooves perfect in pitch diameter, many as well as few ropes can be run on a drive with good efficiency. With the American system, increasing the slack rope tension up to 360 lb. in a 1-in. rope does not appear to decrease its efficiency, but rather to increase it, if power be used in conformity with this tension; but only such tension should be used as is necessary to drive the load needed.

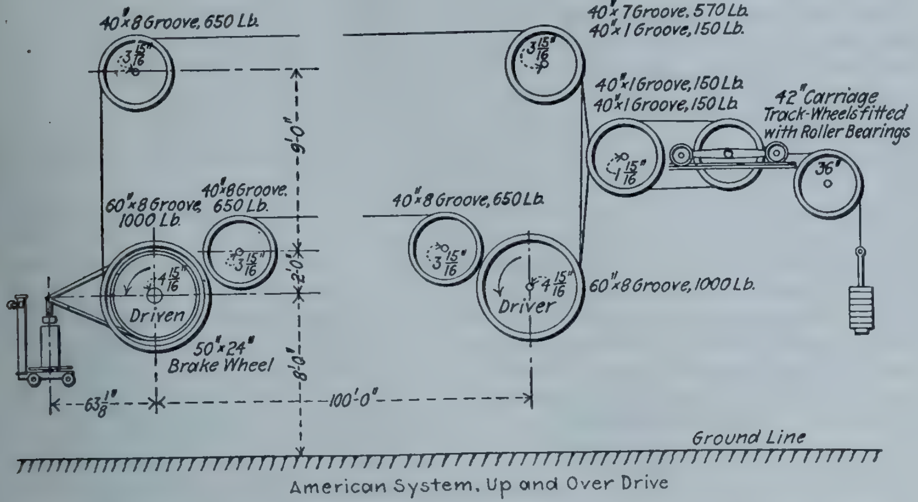

FIG. 2. GENERAL PLAN OF AMERICAN UP AND OVER, OR INDIRECT DRIVE SYSTEM.

The efficiency was measured under full, three-quarters, one-half and one-quarter loads, while one-inch best Manila rope was used. The tests cover drives of from one to eight ropes, with centres from 25 to 150 ft., on both American and English systems; also open or straight drives, as well as indirect, or up and over drives. For the rope tested the American system has very much more capacity than the English system, and has also a higher percentage of efficiency. In general it would appear that, where there is a considerable power to be transmitted, the properly worked out rope drive gives a most efficient and economical method, and where conditions are favorable to its installation no other known method of transmission will so well conserve power losses.

The efficiency as determined includes the losses in the rope itself, the friction in the bearings on the driven shaft, and the losses due to the inertia of the driven wheel and the prony-brake wheel, and, also, in the American system, the friction of the tension equipment. All tests were made to include the friction of the receiving shaft and bearings as if it was thought this would more nearly approximate working conditions and make the data obtained of more general application in ordinary comparisons. All bearings used were of the ring oiling babbitted type, and the ropes were all 1-in. Manila rope of best quality, carefully treated with a rope dressing to prevent the entrance of moisture and to keep the surface in as nearly uniform condition as possible. It was found during the test that this was of great importance as very slight changes in the rope surface immediately affected its capacity and efficiency.

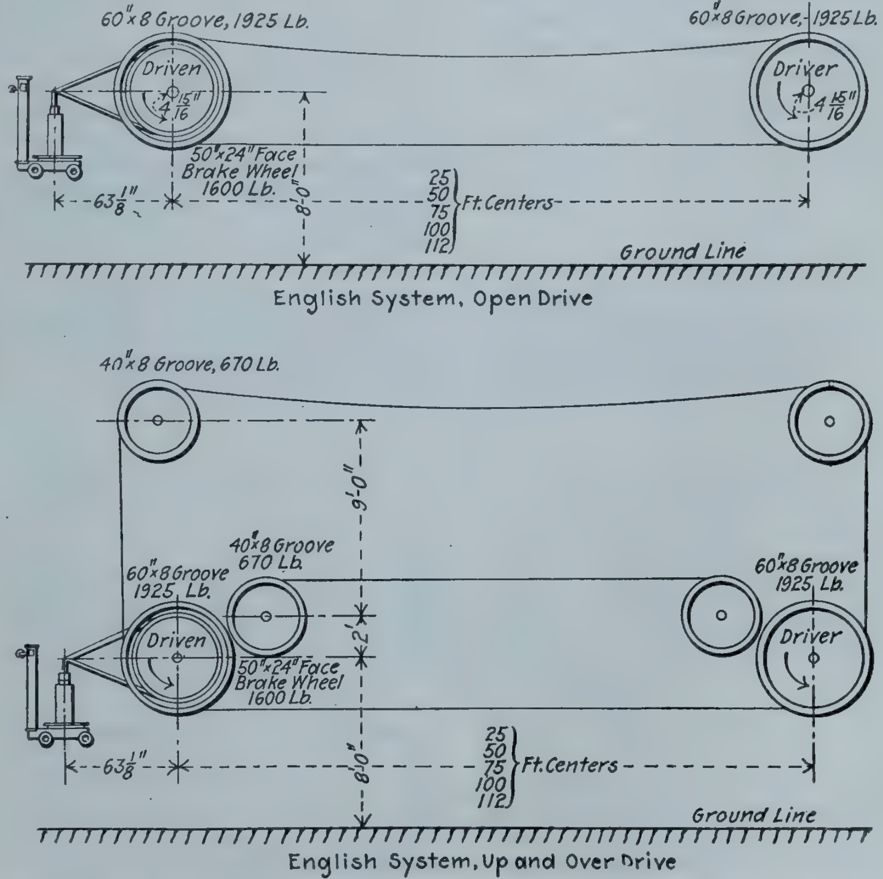

FIG. 3. PLAN OF ENGLISH OPEN DRIVE AND "UP AND OVER" DRIVE SYSTEMS.

With the American system, a lower efficiency is shown on the lower number of ropes. This is undoubtedly caused by the fact that the eight-grooved wheel made for testing eight ropes was used for all the lesser number of ropes to avoid the expense of making additional wheels with a suitable number of grooves for each drive. This together with the weight of the prony brake increased the proportional friction on the smaller loads, and is, therefore, a larger percentage of the total load in the drive of few ropes. With the friction of driven shaft eliminated, limiting the losses to those in the rope alone, it is believed the efficiency in a single rope would be as great, if not greater, than any multiple thereof.

In all of the above tests the tension in the slack side of the rope was kept as uniform as possible at 180 lb. by means of weighing the tension carriage properly. In order to ascertain what tension would give the greatest degree of efficiency, irrespective of life of rope or wearing qualities, a test was made with the slack rope under varying tensions. This was determined on one rope because the capacity of the single rope was, under the heavy tension, as great as that of the motor, so no proper comparison could be obtained on more than one rope.

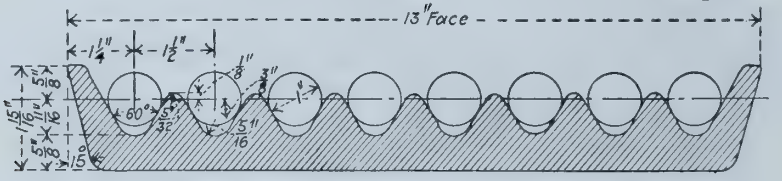
Groove Pitch Feature.

One of the greatest troubles in rope driving, when installed by inexperienced engineers, has been the lack of uniformity in pitch of the grooves where many ropes were used. This differential in the grooves compels slippage of the ropes which not only causes loss of power, but also rapidly depreciates the rope, and often causes the rope to flop around badly. To test the loss of efficiency in this case, two wheels 60 in. in diameter, of eight grooves each, were made up exactly alike so far as could be, and after most careful measurements the grooves on either wheel were found not to differ more than 1/64 in. in circumference from any other on the same sheave, and a test made. The driver was then removed, and the pitch diameter of each groove made approximately 1/32 in. less than the preceding groove so the eighth groove was ¼ in. less in diameter than the first one.

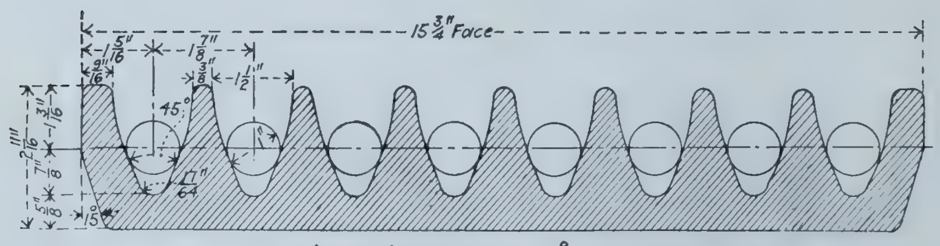
Again, it was placed on the driving shaft and a duplicate set of tests made. In this test as the first groove was ¼ in larger in pitch diameter than the eighth groove, with the sheave revolving at 160 r.p.m., there would necessarily be a slippage in an inelastic band of over ten feet per minute. The photographs taken of this differential drive, show plainly the sag of the various ropes under this condition, and how, under heavy load they stretch and slip in the grooves of the sheave. The elasticity of the rope in this case undoubtedly lends itself to aid efficient operation.

Test Procedure.

The "up and over" American drive was tested because it is typical of all but direct drives, i.e., straight from driver to driven, and the difference in efficiency between this type and the open drive will serve as a basis of comparison where but two additional right-angle turns are introduced requiring four additional idlers. This test was run on approximately 100 ft. centres with a new rope, the same rope being afterwards used in the testing of the various English drives.



American Standard 60° V-Grooves



Engineers' Standard 45° V-Grooves

FIG. 4. DETAILS OF GROOVES USED ON DRIVER AND DRIVEN WHEELS.

In testing the English drives, in order that proper comparisons be made, the ropes were all cut to the same measured length, and the splices carefully made, so that all ropes might be equally tight when applied to the sheaves. The movable tower was then carefully moved back, the rope being run slowly meanwhile until the sag in the rope was approximately the same as in the American drive of the same centre distance in which the slack rope was under a tension of 180 lb. This is undoubtedly a higher tension than is used in general practice on the English drive system with this size of rope, and the capacities and efficiencies shown are perhaps higher than are ordinarily attained in common practice. The efficiencies, when compared by speeds, of the English open drive show a marked decrease as the speed of the rope increases, falling as low as 84.5 per cent. at 5,500 ft. rope speed.

The general tendency in all tests made, both English and American, was corroborative of this tendency toward decrease in efficiency as the speed of the rope increases. There was, however, a lack of smoothness to many of the curves owing, it was thought, to variations in rope tension, and perhaps slight changes in the surface of the rope due to climatic changes. This was very much more noticeable on the English than on the American system, the irregularity of the curve on the former being affected by the fact that a greater load was sometimes attained on a certain speed than could later be reached on the next higher speed. The efficiency of the English drive, within the limit of distances tested, remains practically constant irrespective of centre distances; while with reference to number of ropes, it increases as does the American for the first few ropes, and then remains practically constant through the additional ones.

In order to test the effect of tension on the English system, a comparison was made by moving the receiving tower forward 1¼ ft. after making a series of tests, and then making another corresponding series. When sheaves with proper English pinch grooves, as shown in Fig. 4, were used, there was no appreciable difference either in power transmitted or in efficiency. Greater variations than 1¼ ft. in centre distances could not be satisfactorily tried because of the slack ropes dragging on the ground.

A new rope was used on the American open drive, another new one being started with the American "up and over," which latter was also used on both the English drives. The time of introducing the new rope is mentioned because it was found that a new rope had very much less capacity, owing to its low coefficient of friction, than the same one had after it had run a short time in work, and having less capacity it would usually have less efficiency also. The stiffness of the rope when it was new also seemed to add friction to the drive owing to the bending action in passing around the sheaves, which on the test were only 60 ins. in diameter. With larger main drive wheels, where the rope is not bent to so small a radius, the efficiency would undoubtedly be slightly increased over the results here shown.

Rope Drive Capacities.

The capacities of rope drives are affected by so many variables that no particular attempt is here made to state capacity other than in general figures.

Limiting capacities obtained are in no sense to be considered as available working capacities, but merely as limits reached in driving capacities, the practical working capacity being much lower than the limits reached. It is to be regretted that the power available was not great enough to get the larger capacities, as so few points were obtainable on the American open system. Even at the low speed of 2,500 ft. four ropes could not be made to slip with the 250 h.p. available.

The irregularities of these limiting horsepower capacities are caused by many variables, some of which are weather, surface conditions of rope, condition of rope wheel grooves, etc. In connection with the groove in the wheel, it was found that if a rope began to slip in a groove and warmed it up slightly, the coefficient of friction seemed to decrease very rapidly, and if a limiting test were made under these conditions it was invariably much lower than if it were taken just before the rope started to slip. As each test had to be taken in its scheduled order, some of those dealing with limiting capacities were taken at intervals of several weeks.

As the limiting capacities of the English drive are very much lower than the American, it is thought the efficiency is likewise affected, the friction in the former case being a much larger proportion of the power delivered. Again, the English system in order to get driving power in the rope, pinches it in the narrow groove, requiring considerable force to withdraw it again. This effort being exerted continuously uses up considerable power. The American system, on the contrary, uses a 60-deg. groove, in which the rope lies freely and withdraws without effort.

MODERN GEARING.

MR. H. HUBERT THORNE, in a paper read before the Junior Institution of Engineers recently on Modern Gearing, said: The subject had not received the serious consideration of many engineers, partly because of the belief (due to the very indifferently manufactured gears of even recent date) that all gears were inefficient, and partly because a very considerable amount of time must be given over to test and study if the subject were to be mastered. The involute possessed advantages over the cycloidal tooth for general use, as the centres of a gear could be varied to some extent, and still the latter would mesh properly. All that happened when the centres were extended was that the pitch point was moved nearer to the outside of the teeth, the pitches being correspondingly increased. This was a very useful property of the involute, and today this form was almost universally used; so, when speaking of gears, he would consider only involute gears.

The introduction of high-speed motors and the general speeding-up of machinery introduced new problems to the engineer, and he set about to find a gear which would run at a high velocity without undue noise and vibration, and one which would give a fairly high ratio of reduction in a single pair of wheels. Two ways of getting over the difficulty presented themselves—one by using pinions of special materials which would not create noise when running with metal wheels, and one by altering the form of the teeth. The former method was adopted for many drives, and pinions of raw hide, compressed paper, compressed linen, fibre, etc., had all been tried, but on account of the large diameters necessary to accommodate rivets between the bottoms of the teeth and the bore, the wheels became unduly large and heavy, and the ratios obtainable only small. The latter method had also been largely adopted, particularly within the last decade, and had resulted in the development of two distinct forms of gearing—the first worm gearing, and the second double helical gearing.

Worm Gearing.

Worm gearing was quiet in operation, and could be made with ratios as high or even higher than 100 to 1, but owing to the fact that the rolling action of the correct spur gear gave place to a rolling and rubbing action between the worm and the wheel, the speed of the worm must not exceed comparatively low limits, determined by the conditions under which it had to work; and, further, the efficiency went down as the ratio increased, and a high ratio worm gear was not by any means an efficient mechanism. The reasonable adoption of worm gears was consequently restricted to comparatively small powers, speeds and ratios. For such gears, having both shafts mounted in ball bearings, efficiencies of 95 per cent. were readily obtainable.

Helical Gearing.

For high powers and speeds some other form of gear must be looked for than worm gears. The single helical gear possessed the great disadvantage that end thrust was set up along the shafts (a disadvantage also inherent in worm gears), and to overcome this, two single helical gears of opposite hands were riveted or bolted together, thus forming the double helical gear. This type of gear, which was not now built up from two single helicals, but cut direct from the solid blank, was often manufactured with a ratio of 25 to 1 in a single reduction.

By comparison, the variation of stress on the teeth was very much less with the double helical than with the straight tooth, and consequently the former was the stronger. With double helical gears the average engagement was spread over an area, the limits of which were comparatively near the pitch line, and the action became more nearly a pure rolling one, and the rubbing action, which must produce wear, was reduced to a minimum.

With spur gears, particularly when the pinion had only a few teeth, a distinct knock was noticeable, as the load was repeatedly applied along the whole length of the tips of the teeth, whereas with double helical gears, however small the number of teeth in the pinion, the engagement at the top of the tooth could only occur at a particular point or points of the face at any one time, the average engagement being always near to the pitch line. Owing to the elimination of most of the losses due to sliding friction, practically the whole power put in was transmitted through the gear, and from actual tests it was ascertained that with a ratio of 20 to 1 in a single train, the efficiency was 98½ per cent.

Many double helical gears were now running at ratios of 25 to 1 and over, the only limiting factors being the diameter at the root of the pinion teeth, necessary to resist torsion and bending, the capacity of the machine on which the wheel was to be cut, and the space available. The diameter of the pinion was only limited by the necessary root diameter, because, as previously stated, by suitably increasing the face width of the pinion any desired number of teeth would be in engagement at one time.

ICE INFLUENCE ON WATER-POWER DEVELOPMENTS.

IT has been confidently predicted by a well-known engineer that at no distant date Canada will have not only transcontinental railways, but a transcontinental water-power system.

If this prophecy be ever fulfilled—and it would appear to be on the way—its realization will be in a large measure due to the work of men like Prof. H. T. Barnes, of McGill University, who gave a lecture last week, at the Engineers' Club, Toronto, on "The Influence of Ice on Water-power Developments."

Dr. Barnes is more or less of a theorist, and conducts his experiments chiefly from a scientific point of view, but his theories have proved very valuable in practice, and have been carried into effect in practical commercial undertakings. Mr. Murphy, of Ottawa, has admitted that some of the best results from experiments he has made in connection with power houses in winter have been based upon Dr. Barnes' theories.

The "Frazil" Trouble.

The problem which Dr. Barnes is at present engaged upon, and which he expounded by means of limelight illustrations, is to keep the great northern waterways open in the winter months. He showed by many photographs of ice formation in rivers and rapids how power plants were hampered by the accumulation of "frazil." This "frazil" is a formation which gathers in large, sponge-like masses in the beds of rivers, and rising to the surface, forces the upper ice above the water, and causes packing. Dr. Barnes' experiments included the idea of diagonal booms above the dam, and the forcing of hot air or steam on the surface of the water at the head of the dam.

He criticized the Government's handling of ice-breaking on the St. Lawrence River, and said that the Government thought they knew everything about ice-breaking. He declared that the present ice-breakers were useless, and that the Government had given an order for a new one to a firm that had never made an ice-breaker before.

Electrical Driving of Winding Engines and Rolling Mills *

By C. Antony Ablett, A.M. Inst. C.E. and H. M. Lyons, A.M.I.E.E.

Each inroad made by electricity into fields long held by the steam engine usually marks a distinct advance in engineering science. The authors show that the electrification of mine hoists and rolling mill machinery is not only fully as feasible as that of railways and other well-known applications, but that it has much greater flexibility in admitting of automatic control, safety devices, etc.

THE use of electrical machinery for driving hoisting engines in mines, and reversing rolling mill plants in steel works is comparatively recent; the first winders of importance having been introduced in 1902, and the first electrically driven reversing rolling mill being installed in 1906, though non-reversing rolling mills were driven electrically some eight or ten years earlier. The developments along these lines have been extremely rapid, as is shown by the fact that at the present time about one thousand large winding engines and nearly sixty reversing rolling mills are being driven electrically, and still greater developments may be expected in the future.

Under these circumstances a paper dealing with the modern aspects of the subject and giving the results of the experience obtained in the past would appear desirable.

The earlier winding engines were extravagant in power and had the disadvantage of drawing very heavily upon the source of electrical supply at the moment of starting. It was, therefore, impossible to use them on systems where the supply of current was limited, and even on comparatively large plants their use resulted in serious interference with other machinery. These disadvantages were, however, practically done away with when the Ward-Leonard system and Ilgner's adoption of the flywheel to this system were introduced, but the last few years have seen greater improvements in the Ward-Leonard and the Ilgner system. The present paper will deal chiefly with the development of these systems by the various Siemens companies, who have installed about half the total plants in existence, and with whom the authors have the honor to be associated.

Ward-Leonard System.

A short description of the so-called Ward-Leonard system, illustrated in Fig. 1, is desirable as an introduction. In this system a direct current motor is used to drive the winding engine or rolling mill, the motor being supplied with power from a direct current dynamo. The essential feature of this system is that the voltage supplied to the motor, and consequently the speed of the motor, is controlled by controlling the field current of the generator, instead of by varying the resistance in the armature circuit of the motor. Thus, as the field current of the generator is increased from nothing to a maximum, the motor speeds up from standstill to full speed, and if the field current of the generator is reversed, the motor reverses its direction of rotation. The system enables a very exact control of the speed to be obtained, because the speed of the motor is practically proportional to the strength of the generator field, whatever the load on the motor may be, while with any control system where resistances are inserted into the armature circuit of the motor, the speed would vary within very wide limits with a change of load rendering the exact speed control quite impossible.

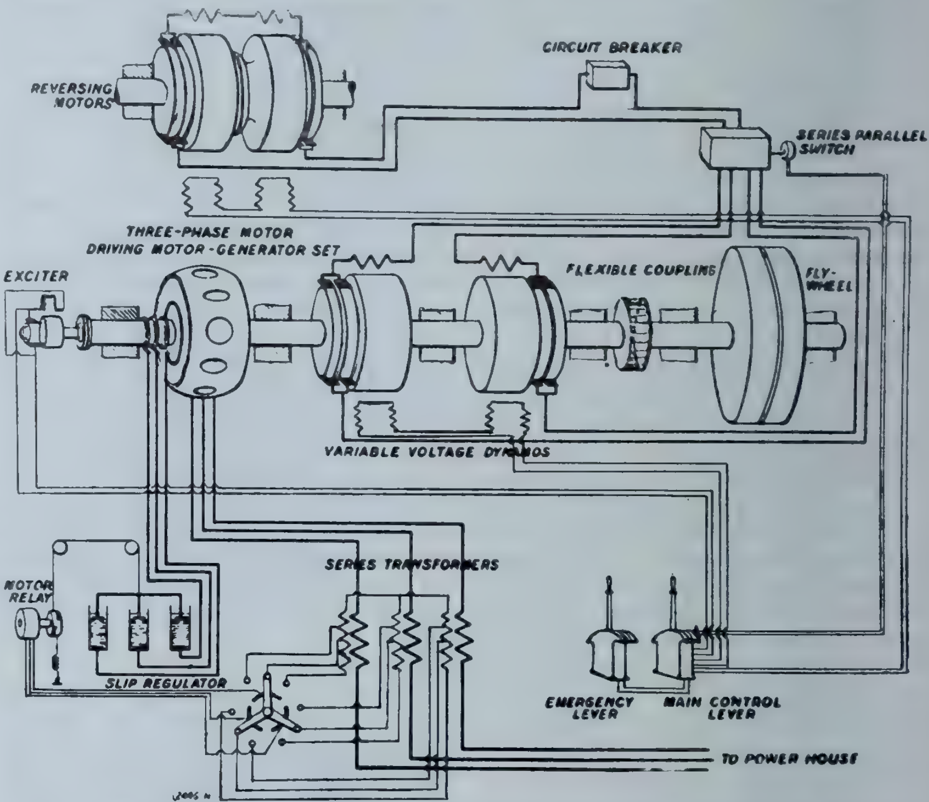


FIG. 1. DIAGRAMMATIC VIEW OF ILGNER SYSTEM OF DRIVING WINDING ENGINES OR REVERSING ROLLING MILLS.

The control of the dynamo field involves scarcely any waste of electrical power, but where resistances are inserted into the armature circuit, the loss of power may be, and usually is, very great. The field currents of the generator are small, so that the control mechanism is small, compact and very easy to handle; the armature currents are perhaps fifty times as great, so that any control mechanism which varies the resistance of the armature circuits is large, clumsy and difficult to handle, in fact a complicated relay system is often necessary to enable it to be handled at all. The dynamo used to supply the motor in the Ward-Leonard system is usually driven by a motor supplied from the available power circuit, forming a motor generator set, and this motor may be either direct current or three-phase, according to the power available. The dynamo may be and sometimes is driven by an engine, water turbine, or other prime mover, if this happens to be more convenient.

Application to Winding Engines and Hoists.

Speed Control. — The main control lever for operating the winding engine is coupled to the regulating resistance in the field circuit of the generator, so that when this lever is in the mid position there is no current in the generator field. As the lever is moved in one direction, the generator field current increases, and as it is moved in the other direction, the generator field current is also increased, but in the opposite sense.

---

*Abstract of paper read recently before the Canadian Society of Civil Engineers, Montreal.

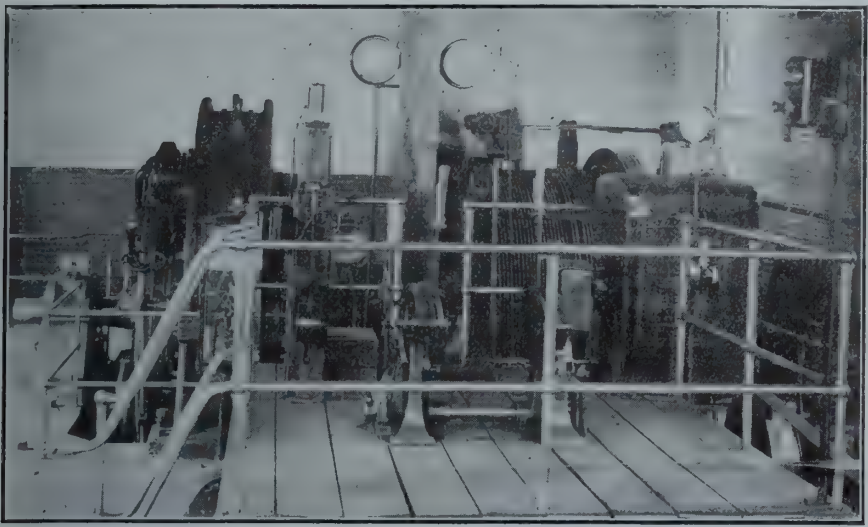

FIG. 2. WARD-LEONARD HOIST, LINGAN PIT, DOMINION COAL CO., SHOWING CONTROL LEVERS AND DEPTH INDICATOR.

From what has been said in the introductory remarks it will be seen that when the lever is in the mid position, the winding engine is at a standstill, and that it starts and speeds up as the lever is moved from the mid position in one direction, while, if the lever be moved from the mid position the other way, the winding engine increases in speed in the other direction, its speed being practically proportional to the displacement of the lever from the mid position, and not affected by the weight of material being hoisted. The driver has not absolute control over the speed, for two cams are provided on the depth indicator, one for each cage, which operate levers coupled to the control lever in such a way as to prevent the cages being accelerated at too rapid a rate, and to slow up the winding engine at the proper point so that the bank is approached at a crawling speed. Provided that these limits set by the cams are not exceeded the speed of the wind is entirely within the driver's control.

Use of Flywheel.

Fig. 4 shows the typical horse-power diagram for a winding engine. The inertia of the drums, cages, head sheaves, material wound, and the ropes, which altogether weigh about 60 tons in this particular case, necessitates a horsepower at the end of the acceleration period of each wind of 1865, which is about three and a half times the average power demand of the winding engine, in this case 524 horse-power, and it is found that the maximum acceleration peak is usually between three and four times greater than the average demand.

The consumption of energy for this Ward-Leonard control rises gradually during the starting period, and the maximum is only reached at the end of the time of acceleration, i.e., from ten to fifteen seconds after the start, because the speed of the winding motor is increased while it is giving the requisite turning moment by increasing the field of the generator, and consequently there is no loss of power in starting.

Since this acceleration peak is of short duration and only comes on gradually, it is possible to supply Ward-Leonard winders from power stations of comparatively small total output, provided that the machines in the power station have a sufficient overload capacity to maintain their speed during peak loads, as is usually the case with steam turbogenerators where the generators are provided with modern voltage regulators.

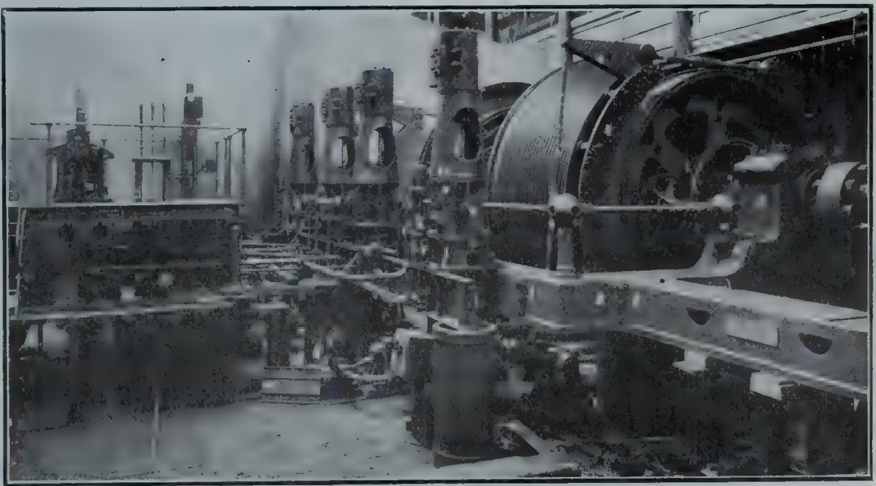

FIG. 3. CONICAL DRUM WARD-LEONARD WINDER, AT THE CANADIAN COLLIERIES COMPANY'S CUMBERLAND COLLIERY, SHOWING BRAKE GEAR AND CONTROL LEVERS. DEPTH, 1,000 FEET; NET LOAD PER WIND, 3½ TONS.

Where, however, this is not the case, and the acceleration peaks of the winding engine are large compared with the average demand on the power station, or where the winder is supplied through a long transmission line from a distant power station, it is sometimes necessary to couple a flywheel to the motor generator set. In this case provision must be made so that during a peak load the motor generator falls in speed, enabling part of the stored energy of the flywheel to be used to supply the heavy demand, and, when the load is small, the motor generator set is speeded up again, the surplus power being taken to restore the energy of the flywheel, so that the demand from the power house or supply system is maintained at about the average. This is the Ilgner system, so-called after the engineer who first used it in practice.

Fig. 5 illustrates the effect of the flywheel in equalizing the load taken by the winder. It will be seen that the current taken by the winding motor varies between +1900, and—1,000 amperes, while the current taken from the supply system is maintained practically constant at 400 amperes, the maximum voltage supplied to the winding engine and the supply voltage being the same.

The following example will give an idea of the power taken by the Ilgner system under practical working conditions with a winding engine arranged to wind 240 tons per hour from a depth of 1,960 feet, making as a maximum 44½ winds per hour, where the flywheel is used whenever the full output is being wound at the full speed, but where a lesser output is being wound at reduced speed, so that the acceleration peaks become less serious, the flywheel is uncoupled to save power. These results are conveniently expressed in terms of the kilowatts taken by the electric winding engine plant per shaft horse-power.

	Output tons per hr.	K. W. per S.H.P.
With flywheel	240	1.49
"	160	1.60
"	108	1.77
Without flywheel ..	160	1.35
" ...	108	1.48

It will thus be seen that, when working the winding engine on the Ilgner system, there is an increased loss of power of from 16% to 17%, as compared with the Ward-Leonard system, and, naturally with the latter where the flywheel is uncoupled, the resistances are cut out of the rotor circuit of the three-phase motor to avoid loss of power.

To avoid misunderstanding of the above results, it should be specially pointed out that shaft horse-power (S. H.P.) is taken to mean the actual work done in raising the load, i.e., if the actual weight of coal or ore, expressed in lbs., which is raised per minute be multiplied by the depth of the shaft in feet, and divided by 33,000, the shaft horse-power is obtained. The shaft horse-power thus does not include the mechanical friction of the winding engine, the sheaves, the guides or the rope losses, and the figure of the kilowatts divided by the shaft horse-power brings in the mechanical efficiency, as well as the electrical.

Details of Ilgner System.

Flywheels are usually designed to equalize the load by falling in speed from 15 to 20 per cent., and it is found that this entails a loss of power in the slip regulator of about 7½ per cent. to 10 per cent. The flywheel is usually coupled to the motor-generator set by means of flexible coupling, though in some very recent Ilgner motor generator sets, where there happens to be no advantage in running with the flywheel uncoupled, the electrical machines and the flywheel are arranged to be carried by two bearings only, reducing the first cost and the friction losses.

Of recent years, the capital cost of Ilgner plants has been greatly reduced, owing to the adoption of higher speed for the motor generator sets, and to the improvements in the manufacture of such flywheels, which enable them to run at very high peripheral speeds compared with those used in the earlier winding engines. For example, the provision of flywheel capacity to equalize peak loads of 60,000 horse-power seconds, in the early days of Ilgner winding, where peripheral speeds of 15,000 feet per minute were used, would require two flywheels of a total weight of about 80 tons, the friction and windage loss of which would be about 150 horse-power. Under modern conditions where the regular peripheral speeds are 27,000 and 30,000 feet per minute, a single flywheel of 22 tons weight would be used, instead of the two flywheels having a total weight of 80 tons, and the friction and windage losses would not exceed 100 horse-power.

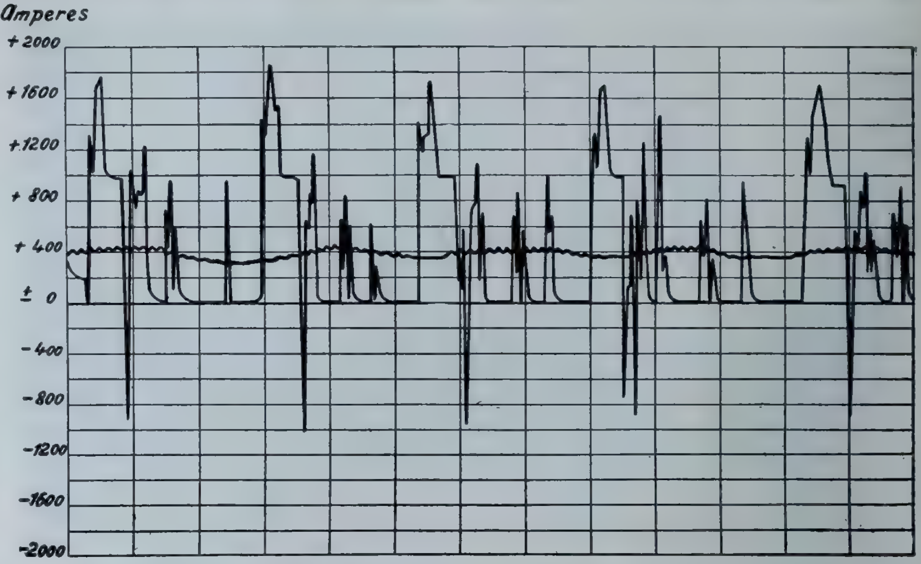

FIG. 5. DIAGRAM SHOWING THE EQUALIZING EFFECT OF THE FLYWHEEL ON ILGNER'S ADAPTION OF THE WARD-LEONARD SYSTEM. THE WAVEY LINE AT ABOUT 400 AMPERES IS THE CURRENT TAKEN FROM THE SUPPLY SYSTEM. THE CURVE WHICH SHOWS THE GREAT VARIATIONS REPRESENTS THE CURRENT TAKEN BY THE WINDING ENGINE.

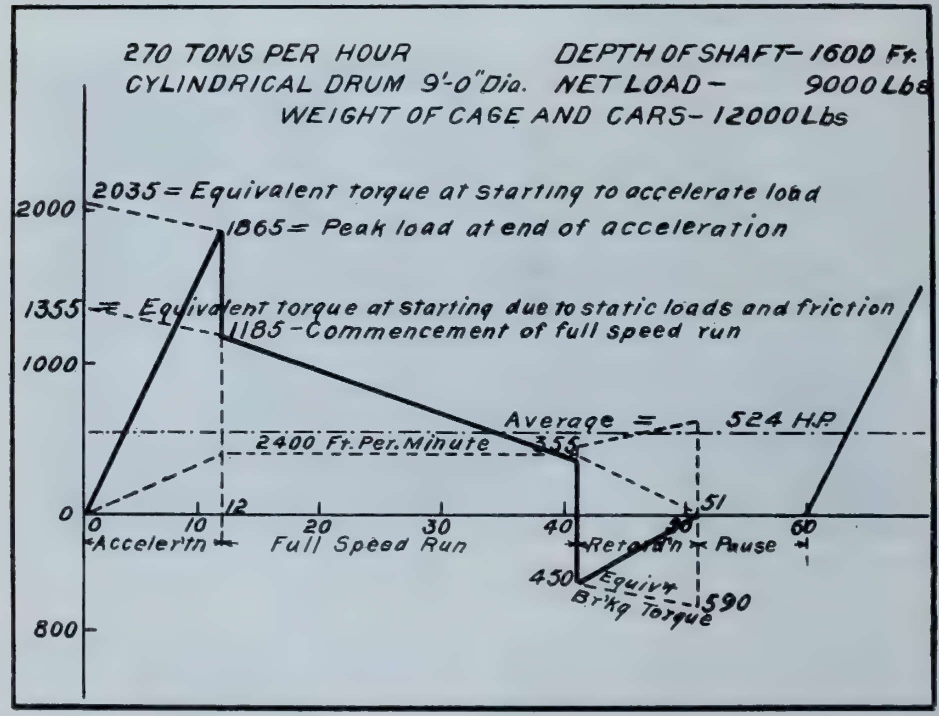

FIG. 4. TYPICAL POWER DIAGRAM FOR A WARD-LEONARD WINDING ENGINE.

The Ilgner system was used on practically all the early European winding engines, but as at the present day, power stations are being installed of much greater capacity than those of a few years ago, and high speed turbo-generators of large overload capacity are being adopted, the Ward-Leonard system at the present time is being used to a much greater extent than the Ilgner system for winding engine work.

The Systems Compared.

Generally speaking, the Ilgner system of winding may be preferable to the Ward-Leonard system in the following cases:—

(1)—When the time occupied by the wind is short.

(2)—For vertical shafts.

(3)—For large outputs.

(4)—Where the winding speed is very high.

The above conclusions may be considerably modified by the nature of the electrical supply. Where the power station is small or the winder is supplied through a transmission line of considerable length, the Ilgner system will be more suitable, but where the power station is large and near the winder, the Ward-Leonard system is the better. Where there are a number of winding engines supplied from the same power station, the Ward-Leonard system would prove very suitable, because the combined effect of these winding engines working together will be to reduce the percentage of fluctuations on the power station load. Fig. 6 gives an illustration of this principle, and shows a case where three rolling mills are supplied from a single power station, and although the load of each one varies about 73 per cent., the total fluctuation in the power station load is about 28 per cent.

Brake Gear.

The mechanical brake is so arranged that, when required to be brought into action, it is actuated by a weight at the end of a lever, but normally held off the drum by an air cylinder. Under normal conditions the cams on the depth indicator actuate the control lever, so that the cages approach the bank at a very slow speed. When they reach the bank, the driver brings them to rest by means of his control lever, and then puts on the mechanical brake to hold the cages in position by means of the brake lever. The brake lever is interlocked with the control lever, so that the driver cannot put on the brake by means of the brake lever until the control lever is at about its middle position, i.e., unless the cages are moving at a comparatively slow speed.

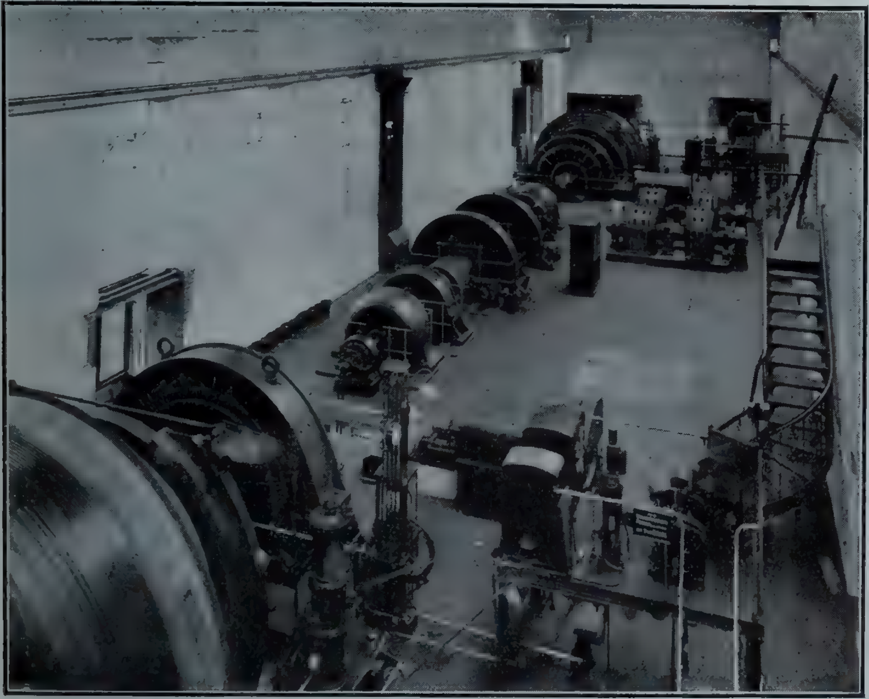

FIG. 6. GENERAL VIEW OF WINDING ENGINE EQUIPMENT, MARKHAM STEAM COAL CO. PLANT, SHOWING BOTH WINDING ENGINES.

To enable the driver to stop the winder in case of any emergency arising, a third lever, the emergency lever, is placed on the driver's platform and, if this be operated, it puts on the mechanical brake through the emergency gear and at the same time cuts off the excitation from the dynamo of the motor generator set.

Safety Devices.

From what has been said, it will be seen that the brake is applied by the positive action of the weighted lever, and, if the air pressure should fail, the brake is promptly put on. The armatures of the winding motor and the generator are permanently connected by heavy cables, and there are no cut-outs or switches in this circuit, so that the circuit between the armatures cannot be interrupted; electrical braking is always available as well as the mechanical brake, unless the excitation should fail.

As mentioned above, cams are provided on the depth indicator which keep the acceleration within safe limits, and the cage is brought gradually to a slow speed by the time it reaches the bank. An overwind device is provided, usually both on the depth indicator and in the shaft, which puts on the mechanical brake through the emergency gear and cuts off the excitation should the cage overwind the bank, thereby bringing the winding engine instantly to a stop. Should the air pressure or the excitation fail, the mechanical brake is put on by means of the emergency gear. When men are being wound the throw of the main control lever is limited by means of a switch on the bank, so that the winding engine cannot be run above a certain speed.

Where electrical driving is adopted, it is very easy to provide safety devices, and all those mentioned are designed to protect the plant against careless handling, but if the majority of safety devices were dispensed with, the Ilgner and the Ward-Leonard winder would still be better protected against careless handling than the steam winder. The fact that it is impossible for an Ilgner or a Ward-Leonard winder to race or run away makes it inherently safer than the steam winder.

EXPERIMENTS ON ROPE DRIVING.

VERY extensive experiments have recently been conducted under the auspices of the Society of German Engineers at the Charlottenburg laboratory. These researches cover a wide field, and of especial interest are those which relate to the influence of velocity. The efficiency in per cent. is given under various tensions, showing a considerable decline at low loads. With a tension of 286 pounds in a rope of two-inch diameter, which is sowewhat below the tension of 200 pounds per square inch commonly employed in calculations, the efficiency is 98 per cent. at 2,540 feet per minute and 96 per cent. at velocities of 7,680 feet per minute.

These experiments conform so nearly with discoveries which were made many years ago as to make it fairly certain that with a properly designed installation and with a good grade of cotton rope the high point of efficiency, which by many tables is indicated to be at from 4,500 to 4,800 feet per minute, may be moved a considerable distance beyond these figures. They also indicate that rope drives can be used to advantage at much higher speeds. Another matter definitely established by the Charlottenburg tests is that idler or jockey pulleys produce a marked loss in efficiency.

The evidence from actual experience, as well as from tests, indicates that it is safe to use proper installations of rope drives up to 7,000 feet per minute, and that the power up to this speed will be approximately in direct ratio to the increase in speed. As an example, it may be mentioned that nine ropes of two-inch diameter are regularly conveying a normal load of 880 horsepower at 7,200 feet per minute in a large steel works in Germany. This is double the amount allowed by many tables in which too much allowance was made for centrifugal force by the compilers. It therefore would appear that the high speed permissible with rope drives is not limited so much by the rope efficiency and endurance, as by the material in the pulleys being able to resist the centrifugal stresses.—Machinery.

The Application of Chain Driving to Textile Mills

By H. T. Hildage, M. Inst. C.E.

About two years ago experiments began to be made in Lancashire, England, on the suitability of Bush Roller and Silent Chains for transmission purposes in textile mills. The new method quickly gained favor, and the present extract from a paper read before the Textile Institute in Manchester gives particulars of numerous typical applications of this latest form of mill drive.

IT WILL be difficult, if not impossible, to convey an adequate or accurate impression of the extent to which chain driving has been adopted in textile mills. Generally speaking, the tendency has been to resort to this form of transmission only in cases in which other forms of transmission, for some reason or other, are not suitable or have given trouble. The idea that chain driving is a standard method of transmitting power, of very great value, and of almost general applicability; that it ought to be considered whenever a new plant is being put down, or an old one remodeled, has not received proper recognition either from engineers or from textile manufacturers, and it is only when chain manufacturers have been unusually pushing, or when consulting engineers or mill owners have been unusually enterprising, that the matter has been considered in this way. It can be assumed, however, that in every one of the cases mentioned hereafter, the application of chain gearing has been thoroughly tested and found satisfactory, and may therefore be regarded as one of the standard drives for the future. It will be convenient to arrange these cases under separate headings.

Driving Lineshafts in Spinning and Weaving Factories.

In only a few cases has chain gearing been used to drive direct from the engine to the lineshaft, and in these cases the power has not usually exceeded 100 h.p. It has, however, been very extensively used for driving from electric motors to lineshafts, and its suitability for this purpose has been very completely demonstrated. Perhaps the best example for us to take now is the electric conversion of Mr. Robert Clough's mills at Keighley, Yorkshire, carried out by Mr. W. O. Pepper.

A cross-compound Corliss engine driving by ropes to the head shafts in the usual way was replaced by a turbo-alternator as a prime mover and electric motors as transmitters, without any other alteration in the structure or arrangement of the factory. In every case the shafts were driven from the motors by means of silent chain gearing, and specialists in chain transmission were consulted from the outset, and, as far as latitude was possible, arranged the drives so as to be entirely suitable for chain gearing. Fig. 1 shows a typical drive. The conversion was carried on without any interruption whatsoever to the daily work of the factory. The chain wheels were mounted on the shafts alongside the rope pulleys, and no other

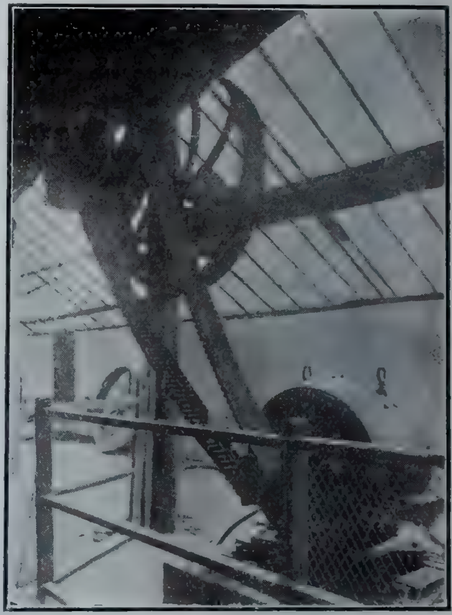

FIG. 2. 90 H.P. CHAIN DRIVE.

FIG. 1. 75 H.P. SPINNING ROOM DRIVE (CHAIN RUNNING).

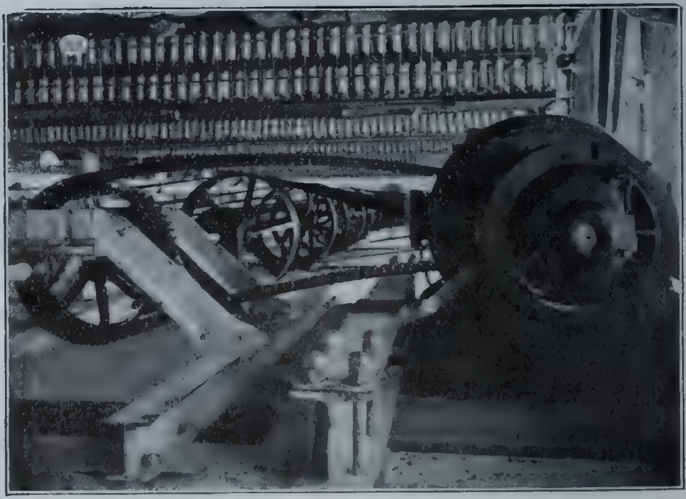

FIG. 3. CHAIN DRIVES IN FLAX SPINNING FACTORY.

alteration to the shafting or mill gearing was made. This fact is of some importance in considering the remarks that follow concerning uniformity of turning, and the descriptions of the tachograph records.

In April, 1911, when these mills were still running under the old conditions, a series of tachograph diagrams were taken from the shafts near the rope drives, and in March, 1913, after the mills had been running for some time with electric power, a further series of diagrams were taken from the same shafts near the chain drives. It was found by a comparison between the tachograph records taken in the same place, on the same shaft, before the conversion and after, that the cycle variation was very much reduced. The comparative figures are given in the following table:—

Where taken, and nature of load.	Per cent. Speed Variations.	
	Rope and Reciprocating Engine.	Chain and Motor.
Near engine, spinning room, second floor, steady load	.5	.0
Further from engine, spinning room, fourth floor, steady load............	1.2	.0
Near engine, weaving shed, fluctuating load	4.5	.5

Note.—The author here introduces a number of tachograph diagrams, which lack of space forbids our reproducing in **The Power House.** They are chiefly of interest to experts, and serve to show in a graphic form the great improvement brought about in the regularity of turning by the installation of the turbo-alternator set combined with chain drives. One of the inferences to be drawn from the diagrams is that where steadiness and even turning are of importance, it is advisable to place the motor and chain drive as near the middle of the shaft as possible. After discussing the diagrams at some length, the author continues as follows:—

As Mr. Clough's installation embodies many novel features, it has naturally been kept under close observation by those directly interested, and now, after considerably more than a year's running, it is possible to say that, as far as chain gearing is concerned, the results have proven even more satisfactory than was originally anticipated.

Another rather interesting drive is shown in Fig. 2. This is a 90-h.p. drive in the central finishing works of the Calico Printers' Association. The shaft was originally driven from the same motor by a belt, through a first reduction in spur gearing. It is obvious that, had chain gearing been used in the first instance, there would have been a considerable reduction in the first cost of the drive, and it is possible that some of the space occupied by the belt drive might have been used for other purposes.

Another drive that is interesting, because it shows another form of construction, is Fig. 3. This is in a flax spinning factory, and the looms were formerly driven—before electrification —by vertical shafts and bevel gearing. After electrification spur drives from the motors were first used, but the vibration and noise was so great that they had to be taken out.

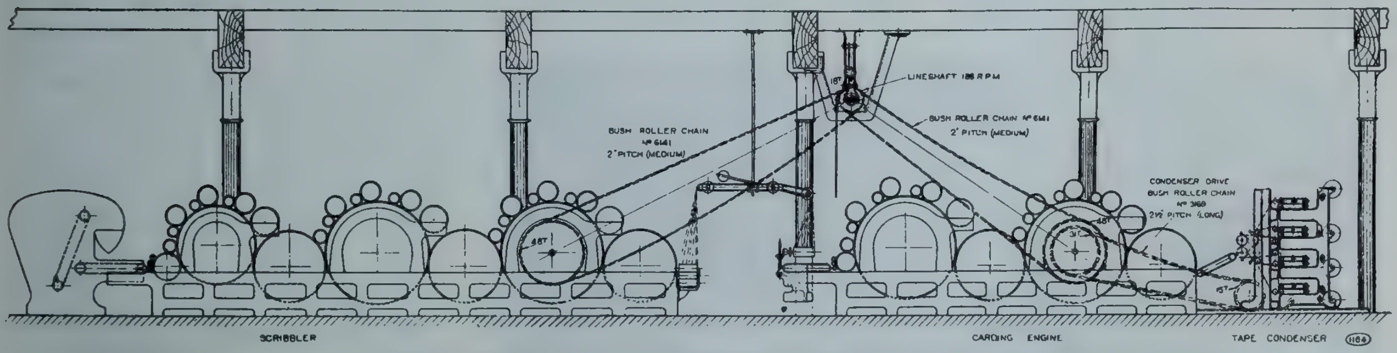

FIG. 4. CHAINS DRIVING SCRIBBLING AND CARDING MACHINES.

Driving from Lineshafts to Machines.

For several reasons the substitution of chains for belt driving from line shafts to machines has not been very much taken up by textile manufacturers. In the first place, it is rather a radical proceeding, and mill owners are conservative. The advantage to be obtained from a single substitution appears very small, and extensive substitution could naturally only be taken up after experiment and experience. Chain manufacturers, on the other hand, have not devoted much attention to pushing this kind of business, because in the present state of the knowledge of chain gearing they realized that they had tremendous difficulties to overcome, and a much more natural line seemed to be to push the sale of heavy drives, which gave them the business that they wanted immediately, and served a useful purpose in educating those interested in the subject of chain gearing. There is no real reason, however, why it should not be taken up very extensively indeed, and with very great advantage. There are some cases which present no difficulty whatever, from a chain point of view, and immediate benefit would be obtained.

One of the cases in which it has been applied is of striking interest to woolen manufacturers, namely, the driving of scribbling and carding machines. The designers and builders of these machines have been at very great pains to insure that all the various swifts of each unit should be connected up by a positive transmission, for the obvious reason that the product of one unit is the raw material of the next, and must consequently be supplied at exactly the correct rate. In other words, each unit must be capable of taking the product of the machine before it, just as fast as it is produced. In spite of this obvious necessity, and the great pains taken to meet it, the units are usually connected to the lineshafts by belts, and the condenser connected to the swift of the last unit by belts or bands. These belts or bands, which all slip to some extent, are often of different lengths, and differently loaded, and even if they were all the same length and equally loaded, their condition, as regards the presence of "fly," or as regards tightness, would cause them to slip differently.

Messrs. William Lawton, Ltd., of Huddersfield, were the first to conceive the idea of using chain gearing for the purpose of driving these machines. They tried it on one set in their own mill, with entire success. A comparison was made between this set of machines, and another set with belt drives, running under, as far as possible, identical conditions, for a period of 21 days, and there was found to be an increase in production of 4.3 per cent. Mr. Lawton also said that a considerable improvement in the quality of the material was found, which showed itself in the reduction of the number of broken ends in the spinning room.

In a more recent case, when the change was first made it was found, after 15 minutes' running, that the scribbler was overmaking the carding engine, and the feed into the latter had to be speeded up 7 per cent. In the two days previous, the feed on this particular machine had to be changed four times to allow for the varying slip of the main belt on the scribbler. During five hours' running, after the conversion to chain driving, two ends came down in the condenser, whereas the average before the conversion was made was in the neighborhood of three per hour.

No modifications of the arrangements in the carding room are necessary for the purpose of making this kind of conversion. A friction clutch mounted on the lineshaft is substituted for fast and loose pulleys on the machine, and it is desirable, on account of the heavy starting torque, to use a gradual engagement device for operating the clutch. The chains can then simply take the place of the belts. A typical example is shown in diagram Fig. 4.

An example of driving from the main shaft to a small auxiliary countershaft for mules is shown in Fig. 5, while Fig. 6 shows some calender drives that were installed in the year 1907. These are still running, and giving great satisfaction.

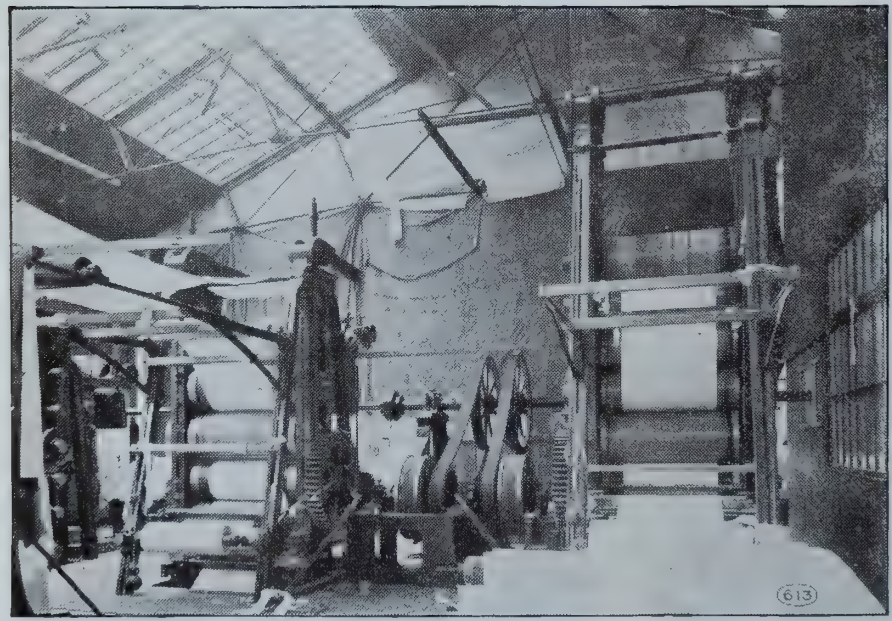

FIG. 6. CHAINS DRIVING CALENDERS, INSTALLED 1907.

The next example really lies half-way between driving from lineshaft to machines, and driving from individual motors to machines. It is the case of the installation of the Seedhill Finishing Co., of Paisley, Scotland. Generally speaking, the machines are arranged in pairs, and the driving is from a motor to a countershaft for two machines, and from this countershaft to each of the machines.

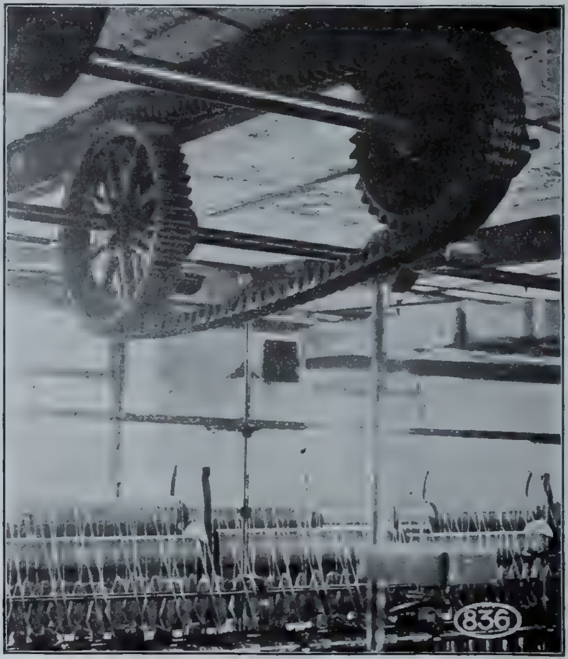

FIG. 5. CHAIN DRIVING FROM MAIN SHAFT TO COUNTERSHAFT FOR MULES.

About the middle of October, 1912, the works of this firm were completely gutted by fire, and in December of the same year arrangements had been made to recommence building them on entirely new lines, incorporating all the latest improvements. Plans were made for work to be re-commenced by May 1st, 1913, and actual pieces of material finished in the new works were being delivered in Lancashire by May 6th, 1913.

We are indebted to Jones & Glassco, Montreal, for the illustrations accompanying this article.

Change of Name.—On and after September 1st, 1914, Jones Cold Store Door Co. will change its corporate name, and will thereafter be known as the Jamison Cold Storage Door Co., Hagerstown, Maryland. No change whatever will be made in the organization or the business of the company, and the personnel of the management, the sales and shop force will be the same as it has been since 1907. The change of name by the Board of Directors was made in compliment to the Jamison family, whose absolute control and management has directed its affairs to its present world-wide fame in cold storage doors. No change has been or will be made in the trade names or trade rights, and all the property and rights which they now possess will continue and be used in the catalogue and all of the advertising matter.

Gas Engine Troubles.—I am of opinion that W. M. Grey's trouble is in his engines and not in the generators. I think the trouble is due to the mixture or the governor, with possibly a little ignition disorder. There might even be a combination of any two of these. If Mr. Grey would state when his engine stops; that is, whether at light load, full load, or over-load, also what kind of fuel he uses and the type of ignition, it would be possible to give a definite opinion of some value to him.—H. W. Benton.

Elements of Power Transmission -- The Belting Feature

By J. Pedie Sanderson, B.A.Sc.

The necessity of a fully competent man to supervise the care of belts is often one of the things about a plant that are so obvious as to be little thought of. Like the engineer who is asked: "Can you start an engine?" and the fireman who is hired for his ability to transfer coal, this man's necessary qualifications are often fulfilled by an affirmative answer to the question: "Can ye fix belts?"

IN spite of the many improvements recently made in electrical transmission and the great advances achieved in other forms of power transmitting mediums, belt drives are still the most suitable for a fairly wide range of conditions, and their apparent simplicity is inclined to cause their popularity to remain with engineers for an indefinite period of time.

The initial cost of a belt transmission is about one-fourth that of an electrical transmission where the conditions are suitable for the former system, but where the drive is such as to cause more or less rapid deterioration of the belt material, the balance of favor goes to the electrical drive. A leather belt drive costs nearly twice as much as a rope drive, and more where large powers are to be handled for considerable distances. Rope drives, however, unless great care is exercised in their construction are very much less economical.

Rope Drive Comparisons.

As the ropes wear they become uneven in diameter and some parts fall more deeply into the V-shaped grooves of the sheaves than others, causing different speeds in different sections of the rope. This sets up a sort of differential drive which causes a difference in rope tension and may even cause some ropes to be tighter on the slack side than on the intended tight side of the drive, and consequently producing negative work. Leather belts can be efficiently spliced much more easily than cotton or rubber belts, and the splicing up of a rope drive is a very considerable undertaking in comparison.

Abuse of Belts.

The value of a belt transmission rests in its durability and efficiency, two qualities almost entirely at the mercy of the treatment which is accorded it. A particular case came to the writer's notice about ten years ago. A three-inch leather belt was placed upon the cone pulley drive of a lathe and, on account of poor alignment and rough usage, had to be replaced with a new one in less than six weeks. Before the new one was put on, however, the pulleys and shafts were correctly lined up with the result that it is still running and rendering good daily service.

The strangest feature in connection with the supervision of belting considering its importance to the continuous and efficient operation of machinery is the fact that, in a great majority of plants, its care is either entrusted to no man in particular, or to some one who has been found to be unsuited for anything else. How often one sees an important drive made up of from three to six pieces of belting of various ages and thicknesses fastened together with leather lacing, wire, and perhaps a number of patent metallic fasteners. The operator in many cases, patches or fixes his belts with whatever he can get, and gives them no further thought as long as his machine keeps going. He rarely has more than a rudimentary knowledge of this class of work.

Belting Organization.

The belting of a plant, no matter how extensive, should be placed in charge of one man, preferably one who has gained his experience in a factory where belts are made, and who with his understudy should in company with others connected with machinery maintenance, be under the direction of the chief engineer or master mechanic. It is only in this way, and seeing that the belt man does his work, that dependable records of belt performances can be kept and efficient systems of inspection be carried out.

Tension Measuring Machines.

By far the most important point in connection with the care of belts is tension properly set and maintained. There have recently been devised and placed on the market several appliances for accurately measuring the tension of belts. One of these is the belt bench which is provided with spring balances and other requisites so that belts can be periodically removed from their machines and be brought to the bench for inspection and repairs, and have their tensions weighed. This is to be advised where the number of belts will warrant the expense, although a great deal can be accomplished by an intelligent man without its use. To supplement the use of the bench, which is limited in its application, there has also been perfected a portable device for measuring the tensions of non-removable belts while in place. As this is applicable only to small belts, and is rather inconvenient to use in some belt situations, it has not, so far, proved very useful.

Proper Tension.

The most suitable tension of a belt is an extremely variable quantity. It should be adapted to its position and to the work required of the belt. The less the tension can be made within reasonable limits without causing slipping, the longer will be the working life of the drive. The experience and judgment of a man suitable for this work has, so far, been found to be the best authority for setting belt tensions.

Belts should be made endless; that is, lapped and cemented together whenever possible. In smaller ones, it is often necessary for convenience in caring for them to have one inferior joint in its length, but there is no excuse for more. This joint should be intelligently made with leather lacing of the proper proportions. Patent metallic fastening devices should be used with caution as a number of them have been found to be worse than useless.

Stretch.

The average leather belt stretches from 6 to 8 per cent. of its original length during its lifetime, and most of this takes place during the first six or eight months of its active use. After this, the stretch is small and uniform until all elasticity is lost.

The method of procedure then for a moderately large belt would be to cut it from a foot to three feet too short, depending upon its size and length. It is then laced up with a carefully made patch which can be periodically shortened until the greater part of the stretching process is finished. A permanent patch is now cemented in and the drive will require attention only at long intervals of time thereafter.

It is well known that a lapped and cemented joint will last more than twice as long as any other, besides running more smoothly and in fact, it can be made as strong as the body of the belt. When the simplicity of making a first-class cemented joint is known it is surprising that it is not more generally used. The requisite tools are comparatively few and inexpensive, as it is possible for an intelligent man to make most of them for himself.

Cementing a Joint.

Before cementing a joint, the belt should be placed over the pulleys and the proper tension obtained by means of clamps. Care must be observed to fasten these clamps squarely across the belt and to locate them centrally with it before drawing them up with the threaded rods along the sides. After drawing the belt a little tighter than is desired to allow for slack, place a smooth board under it between the rods and bevel the ends to form the lap. Apply the cement while very hot, but not boiling, and not too thick, rubbing it in thoroughly. On large belts, it is better to cement a few inches at a time, rubbing and hammering each part down by itself, and so proceeding until the joint is completed. The clamps should remain in position for at least an hour or as long as convenient. Small and medium-sized belts can be readily clamped with C clamps between two smooth boards to which they have been tacked in the proper position. The length of the lap should vary with the width of the belt, general practice being given in the folowing figures:—

Belt widths in inches....	2	3	4	5	6	7	8
Length of lap in inches..	5	6	6	7	8	8	9

For widths of 9 inches to 18 inches, the lap is made equal to the belt width. Above 18 inches, the length of the lap need not be greater than this.

Direction of Lap.

The direction of the lap should be such that, in a single belt, the leading edge of the lap should be on the inside or next the pulley. In a double-ply belt, the same rule applies with regard to the outer layer. The trailing edge of the inner ply, however, should be next the pulley which gives the joint the form of a broken V with the vertex pointing in the direction in which the belt is intended to travel.

Friction is much greater between similar than between dissimilar substances, hence much is to be gained by covering pulleys with leather. This allows a greater horse-power to be transmitted without increasing the tension of the belt, as well as to greatly reduce the tension necessary to transmit a given horse-power. To cover a pulley with leather, make the covering in the form of an endless ring whose circumference is about ⅛ inch to the foot less than the circumference of the pulley. Clean the surfaces of all grease by washing with benzine, naphtha or similar substance. Start the pulley into the ring and cover with a special glue both the inside surface of the ring and the exposed surface of the pulley. Quickly drive the cover over the pulley by lifting it, and striking the cover edges against the bench or floor. When in place, rub the cover thoroughly with a smooth hardwood stick or hammer handle to insure perfect contact, particularly around the edges. If properly done, no pinning is required although it is customary to insert a few copper rivets.

Choice of Belts.

Narrow, thick belts are much more desirable than wide thin ones, especially for long drives. According to Mr. F. W. Taylor, whose experiments cover a continuous period of over nine years, it is advisable to use double belts on pulleys 12 inches or over in diameter and triple belts on pulleys 20 inches or over. This is for the purpose of giving a sufficient stiffness to prevent snapping and waving on the slack side when running at high speeds which is often more injurious than the actual work the belt has to do. This stiffness should also be sufficient to prevent side travel which becomes excessive when belts are long and the load variable.

Belt Calculations.

The satisfaction of belt drives is greatly increased by their proper proportioning.

To find the width of belt necessary when the horse-power required to be transmitted is known.

Multiply the horse-power by 33,000 and divide this product by the product of the belt speed in feet per minute multiplied by 55 for single, 83 for double or 110 for three-ply belts.

The constant 55 depends upon the arc of contact of the belt on the pulley and varies greatly according to different authorities, that is, all the way from 30 to 65. The above, however, is a reliable figure and is for cases where the arc of contact is approximately half of the pulley. When the arc of contact is not 180 degs., the "effective pull" can be found by multiplying the arc of contact by 55 and dividing the product by 180. Multiply this by 1.6 for double belts and by 2 for triple belts.

Inspection.

The belt man should carry out careful and systematic inspections of all belting at frequent intervals and keep a record of his work. Inspection should be such as to determine if any of the following conditions exist:—

(1)—Whether belting is over-dry or saturated with oil.

(2)—If any laps have begun to open.

(3)—Whether belting is working under proper tension.

(4)—Whether shafting is in line or if a guide has to be used to keep belts on the pulleys.

(5)—Whether afflicted with an overdose of dressing.

General.

Greasy or unduly dry belts should be thoroughly cleaned, the former with naphtha or benzine is necessary, and the latter may have to be scraped free of surface dirt. When a clean surface is obtained, both sides should receive a light coat of approved dressing. These applications should be repeated judiciously until that mellow but not greasy feeling characteristic of proper working condition is obtained.

If laps have begun to open, they should first be thoroughly cleaned with some degreasing substance such as naphtha and re-cemented, not tacked or riveted. If shafting be out of line, the sooner it is fixed the better for the machine as well as the belt. The tightness with which belts are put on pulleys is of fundamental importance not only to the belt but to the bearings that carry it. Improper tensions should be promptly re-adjusted to the least that will satisfactorily transmit without slipping the full load required of the belt. The use of rosin, soap or even an overdose of good dressing is to be rigorously avoided. If a belt will not do the work required of it without such destructive encouragement, it should be replaced by one of the proper dimensions.

All electric motors, engine drives and the like where large belts are used should be so mounted that the centre to centre distances between the shafts can be adjusted to give the proper tension to the belts, or in cases where this cannot be done, an idler pulley should be hung and weighted so that the most suitable belt tension will be constantly maintained.

The labor involved in caring for belts cannot reasonably be placed in the "unproductive" class any more than the capital invested in the belts themselves, for the one is vital to the efficient working of the other. The condition of a belt hanging down and the machine operative waiting for the belt man to turn up is one that could not exist with a properly regulated belt department. This saving alone coupled with the prevention of the loss due to slipping belts, to say nothing of the saving in capital investment, would make it a profitable matter to pay the belt man a very good salary.

Chatham No. 21, C.A.S.E., held their second open meeting for the season on March 19. The various members of the educational committee took up in turn the particular section of the work relative to stationary steam engineering on which they have been giving instruction to the members during the winter. Phonograph selections were interspersed with the foregoing, as also an address by Bro. Chas. Kelly on the work of the Canadian Association of Stationary Engineers. The annual banquet of the lodge was held on April 2, at which a full representation of the members and their wives was present. Following the usual loyal, patriotic and association toasts and a musical programme, dancing was participated in until a seasonable hour.

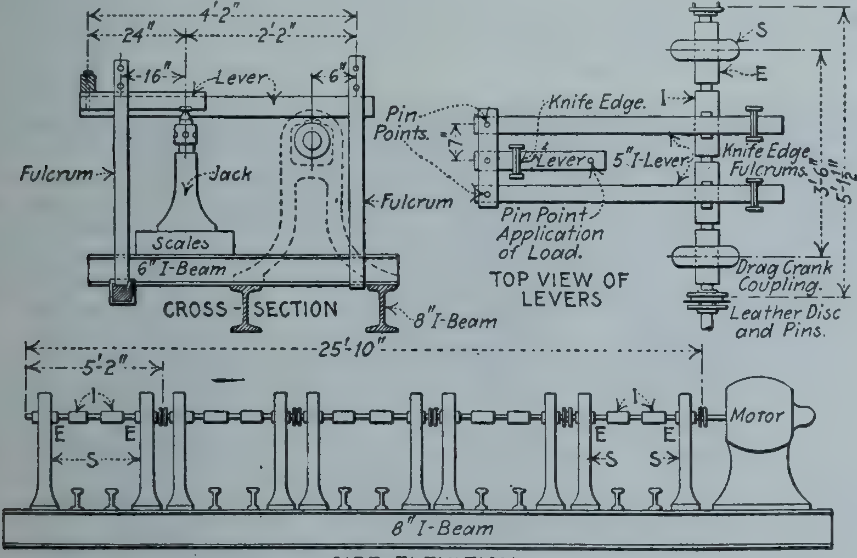
Comparative Tests of Three Types of Line Shaft Bearings

By C. C. Thomas, E. R. Maurer and L. E. A. Kelso.[*]

This paper, read before the A.S.M.E. and published here in abstract, covers experiments made to determine the absolute and relative amounts of power required to drive a series of uniformly loaded and flexibly connected shafts supported successively by three different types of bearings.

THE tests from which the accompanying data is derived extended over a period of four years, and were finally repeated and all results checked by a set of skilled observers, who had formerly no connection with the work. Twenty ring-oiled babbitt bearings supported successively a series of uniformly loaded and flexibly connected shafts, a wide range of loads and speeds being covered and co-officients of friction worked out for each type.

The apparatus was designed and built in the department of steam and gas engineering at the University of Wisconsin, in collaboration with the manufacturers of the bearings, and was so arranged that very exact measurements of power were attainable. All questions of possible lack of alignment, non-uniformity of loading, temperature and quality of lubricant, etc., were given careful study, resulting in the special form of apparatus used.



APPARATUS FOR TESTING LINE SHAFT BEARINGS.

Description of Apparatus.

The apparatus consisted of 25 ft. 10 ins. of line shafting in five equal sections, mounted in hangers (S), which were inverted and used as floor stands, Fig. 1. The hangers were bolted to two 8-in. I-beams. The shafts were of cold rolled steel, 2 7/16 in. in diameter, each section being 5 ft. 2 ins. long. The adjacent sections were coupled together by means of a flexible leather disk or two straps connecting the two flange couplings. The flexible couplings prevented the transmission of any part of the load applied on one shaft to either adjoining section, and also prevented binding between shafts and bearings due to possible lack of alignment.

A direct-current Fort Wayne motor was directly connected to one end of the shafting by means of a flexible coupling. The motor was of the interpole type with the interpoles removed, making it a shunt motor. A water rheostat was used in the field circuit to maintain a constant field, and another water rheostat was used in the armature circuit to vary the speed by varying the impressed voltage. The lost power was obtained first by taking the armature resistance for various currents and plotting a resistance, armature-current curve. From this curve was plotted an armature-I^2R loss, armature-current curve. From this the armature resistance loss for any armature current was obtained. The stray-power loss was obtained by taking a stray-power loss field current curve for each speed; then for any speed the loss for that speed and field could be obtained. By use of this method, the power required to run the motor alone at all speeds, without load, was accurately ascertained, as well as the power required to run the motor and shafts together, at all loads and speeds. The relative amounts of power required to overcome the friction of the various types of bearings were, therefore, accurately determined.

Application of Load.

The load was applied through levers upon hardened knife edges and pin points as fulcrums. Across the top of the 8-in. I-beams and at right angles to them were bolted short 6-in. I-beams to which the fulcrums were attached. The loads were applied to the shaft by two bearings between each pair of hangers. These bearings were identical with those in the hangers, and were supplied with knife edges which engaged a V-shaped groove in the 5-in. I-beam levers. The bearings and hangers for each section were symmetrically placed with respect to the middle of the section; therefore, equal loads on the intermediate bearings (I) produced equal pressures on the end bearings (E). These latter pressures exceeded those on the intermediate bearings by one-half the weight of the shaft, or by 40 lb. This difference is regarded as negligible in the paper, and load per bearing means average of the loads on intermediate and end bearings. The bearings were prevented from turning by short levers fastened to them and resting upon uprights from the floor. Only one type of bearing was tested at a time, so that no complications might arise in establishing the losses for the particular form under test. The reason for using 20 bearings was that the amount of power necessary for a single bearing was so small as to be difficult of exact measurement. Also any single bearing might not as truly represent results from that type of bearing in general as several bearings taken together.

The Bearings Feature.

The three kinds of bearings tested were:—The ring-oiled bearing, manufactured by The Dodge Mfg. Co., lined with babbitt metal made from their formulae; the Hyatt roller bearing, manufactured by the Hyatt Roller Bearing Co.; and the Hess-Bright ball bearing, manufactured by the Hess-Bright Mfg. Co. All bearings were for the same size shaft, and, in fact, the same pieces of shafting were used for all the tests, except that two sections which bent during the tests were replaced.

---

[*] Professor of Mechanical Engineering, Johns Hopkins University; Professor of Mechanics, University of Wisconsin, and Instructor in Electrical Engineering, University of Wisconsin, respectively.

The babbitt bearings were 9 21/32 in. long, and hence their projected area was 22.36 sq. in. The following table is appended for converting total loads used in the tests into unit loads:—

730	1230	1730	2230 lb. per bearing
33	55	78	100 lb. per sq. in.

These bearings were oiled by the well-known ring-oiler device, two rings in each bearing.

Each roller bearing contained six right-hand and six left-hand rollers, .78 ins. in diameter; six being 9 9/16 ins. long, and six being 9 3/16 ins. long. They were of the type in which a cage is used for holding one-half the rollers. Each ball bearing contained a single set of balls, 9/16 ins. in diameter, while the diameter of the inner race through the ball groove was 3.4729 inches. The power was measured by the ammeter voltmeter method, while mercury thermometers (two in each babbitt and roller bearings and one in each ball bearing) were used for measuring the temperature of the oil or bearing.

The speeds used in the tests were between 150 and 450 r.p.m., corresponding respectively to about 100 and 300 ft. per minute peripheral speed. Most of the loads used were between 700 and 1800 lb. per bearing, corresponding respectively to about 30 and 80 lb. per sq. in. for babbitt bearings. All statements of results, therefore, are subject to the above limitations as to speed and loads.

Two lubricants were used in all the tests—Atlantic red engine oil in the babbitt and roller bearings, and No. 2 Keystone grease in the ball bearings.

Results of Tests.

For all conditions of load and speed the power decreased with increase of temperature, but the rate of decrease at the highest load and speed was more marked in the case of the babbitt bearings. At the lower speeds the power did not vary at all with the temperature, practically speaking.

Table 1.—Relative Amounts of Power Consumed in Friction.

	100 Ft. Per Min.		300 Ft. Per Min.	
Bearings.	77 Deg.	100 Deg.	77 Deg.	100 Deg.
Ball	1	1	1	1
Roller	2.2	2.5	2.7	3
Babbitt	3	3.6	4.5	4

In a comparison of the babbitt, roller and ball bearings for 100 degs. and 77 degs. temperature, it was shown that the power for the babbitt is higher than for the other bearings except perhaps at low loads and speed, and that the power for rollers is higher than for balls. The excess of power for babbitt over rollers and rollers over balls increases with increase of speed for all loads. Table 1 shows the relative amounts of power consumed in friction by the three kinds of bearings at the speeds and temperatures indicated. The relative numbers are based in each case on the average power for three loads: 710, 1210, and 1710 lb. for balls; 740, 1240, and 1740 for rollers; and 730, 1230 and 1730 for babbitt.

Breakdown Tests.

In order to observe the performance of the bearings under extraordinarily heavy loads, breakdown tests were run on each type of bearing with only one section of shafting, on which were four bearings. This small number of bearings was used because it was impracticable to keep close watch of a larger number of bearings and avoid trouble during the excessively severe conditions. The maximum load was 600 lb. on the scales, or about 5000 lb. per bearing.

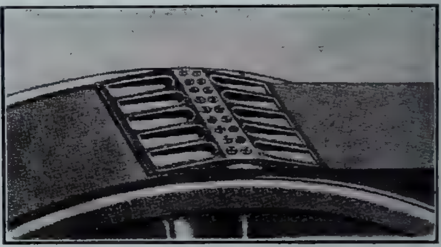
The speed of 200 r.p.m. was chosen because it represents about the average lineshaft speed in practice. These tests began at about 3200 lb. per bearing. Failure occurred at about 4250 lb. per bearing in the case of the babbitt, 4650 lb. in the case of the ball bearings, and about 5100 lb. in the case of the roller bearings. The quality and amount of lubricant used undoubtedly have an important effect upon the load that will cause a given bearing to fail.

The bearings did not in any case "fail" structurally, as the power was cut off soon after distress was manifested, but the failure was simply that of the lubricant. Breaking down of the lubricant results in an immediate increase of the power required to maintain the original speed of rotation of the shaft in the bearings. In each case probably only one of the four bearings used in the breakdown tests showed distress at any one time. In the case of ball bearings, this was evident, as distress was manifested by disintegration of the grease which "melted" and ran out of the bearing. This was accompanied by an immediate increase in power requirement. The temperatures given (99 deg.-117 deg., etc.) indicate the averages for the four bearings being tested. Similar behavior on the part of the babbitt and the roller bearings indicated that at least one of the four under test was suffering from an approach to "metal-to-metal" contact. The bearings were not injured by these endurance tests, and all were used in subsequent tests at the more usual speeds and pressures.

STEEL DRIVING BELTS.

WHILE engineers generally have been devoting a good deal of attention to improvements in chain and tooth gearing for transmitting power, says The Engineer, a new system of belt-driving has been introduced in Germany which appears to possess many advantages over some of its older rivals. We refer to transmission by means of steel belts on the Eloesser system.

These belts are made from a specially-hardened carbon steel having a very high tensile strength. The belts vary in thickness, and are made in widths between 1½ in. and 8 in. The tension required is determined with very minute accuracy by a special instrument, and only one flexible steel joint is used. The belts run on flat pulleys, which are covered with a composite layer of canvas and cork. They are only about one-sixth of the weight of leather belts or ropes suitable for transmitting similar powers, and there seems to be no practical limit to the speed at which they can be run.



JOINT FOR STEEL BELT.

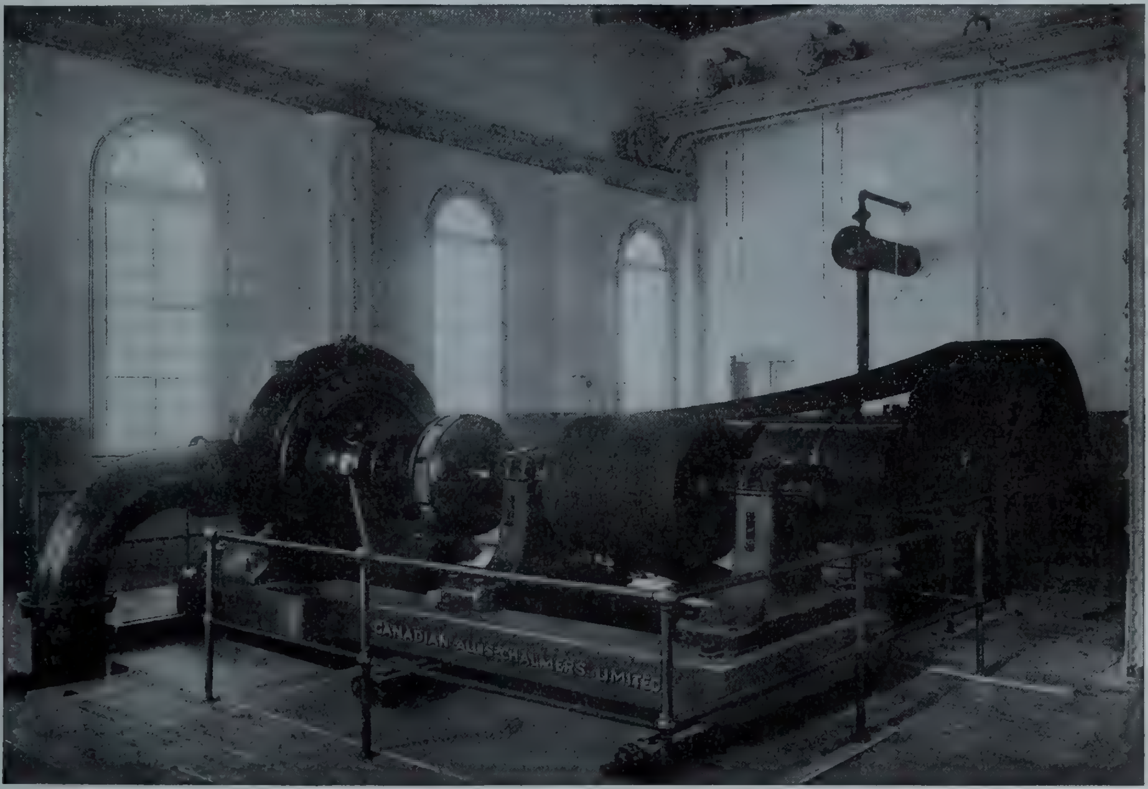
So far, it has not been found feasible to use these belts with fast and loose pulleys, although they are suitable for employment with friction clutches. Neither is their adoption recommended for cross-belt work where the distance between the centres of the pulleys is less than eighty times the width of the belt, nor for very small pulleys, on account of the bending stresses set up. For continuous drives, however, no matter how close or distant the centres, and either horizontal or vertical, the steel belt has been applied with remarkably efficient results. It is claimed that a steel belt is only about one-third the width of a leather belt for corresponding power, that it does not stretch even with years of work, and, as there is no measurable slip, the transmission is uniform and invariable.

In order to convert pulleys from rope driving to steel belt transmission, a stout steel band is strained round the pulley rim and fastened to a plate fitted into a small cut-out section of the pulley grooves. The smooth surface thus formed is serrated and provided with a friction covering of the kind referred to above. The method of jointing consists of a special clamp mounted on the ends of the belt, and after the required tension has been applied, the ends are threaded between an upper and lower steel plate shaped to suit the pulley profile until they abut. The clamping plates are then closed by a number of countersunk screws, and soft solder is run into the joint to prevent the screws from slackening. The edges of the belt are rounded off, so that it can be safely handled while running.

The belt is being introduced into Great Britain by the Power Pulley Co., Ltd., Union Works, Manchester, which has already fitted up several large cotton mill drives in the Manchester district on the system with excellent results.

ROPE DRIVE—GAS ENGINE AND BOOSTER PUMP.

THERE has recently been installed at the municipal pumping station, Moncton, N.B., a gas engine driven booster pump. An interesting feature of same being the rope drive which may be noted in the accompanying illustration. The entire equipment was supplied and installed by Canadian Allis-Chalmers, Ltd., Toronto, under the supervision of Mr. John Edington, city engineer of Moncton.



MUNICIPAL PUMPING PLANT, MONCTON, N.B.

The plant includes a two stage turbine pump capable of delivering 3,470 Imperial gallons per minute against 300 ft. head when operating at 750 r.p.m. The pump is mounted complete, with flexible coupling and two pedestal bearings with rope pulley between, on a cast iron base-plate which is provided with slide rails. The slide rails are used to facilitate the adjustment of the driving ropes.

The pump is driven by a rope drive of the multiple or English type, and consists of twenty-six 1 in. cotton ropes. This type of drive was chosen because of its high efficiency and low initial cost. The appearance of the set of ropes as seen in the cut is almost identical with that of a belt, which demonstrates the uniformity of rope tension attained.

The motive power is a "Premier" gas engine ofthe latest four-cylinder side by side Otto type. It is capable of delivering 460 B.h.p. when running at 200 r.p.m., and operating on natural gas. A special speed regulator is provided in the engine so that the speed may be changed instantly from 160 r.p.m. to 200 r.p.m. The water pressure at the pump delivery may, therefore, be changed from "domestic to fire" pressure as required, these pressures being 45 and 110 pounds respectively.

The fuel for the engine is natural gas which is piped to the plant from a local gas-field. An emergency source of supply is however, provided, in the shape of a suction gas producer for operation on pea anthracite. Auxiliary apparatus for "blowing-in" the producer and for supplying compressed air for starting the gas engine is provided.

LOCATING CAUSE OF PRE-MATURE IGNITION.

By R. Bell.

A 300 h.p. 4-cylinder vertical gas engine, after being erected and put into service, was found to pre-ignite very badly in one cylinder. This took place only under heavy load, and when the producer gas used was fairly rich. The line of demarcation between conditions which insured successful operation and those causing heavy pre-ignition seemed to be very finely drawn and the source of the trouble was therefore very hard to locate. The diameter of the cylinders was 14 inches, and it was considered just possible that the centre of the piston in the cylinder that gave the trouble was becoming overheated. The exhaust valve head was also looked upon with some suspicion.

It was finally decided to drill a ⅜-inch tapping hole in the exhaust valve and plug it with aluminum. This done, the engine was started up and run until pre-ignition began. The exhaust valve was now examined and the aluminum was found to have been melted out. This showed that the temperature attained by the valve must have been at least a low red heat. All the exhaust valves were replaced with water-cooled valves and no further trouble was experienced.

It seemed that the critical stage had been reached with this size of engine as engines with 16-inch cylinders gave no trouble whatever.

INSTRUCTION COURSE FOR OPERATORS.

BEGINNING with the May issue and continuing each month thereafter, an Instruction Course for firemen and engineer operators will form a feature of The Power House. The subject discussed in each number will be dealt with in such manner as to make it complete in itself in addition to being relative to the whole, and all interested or engaged in the practice of stationary steam engineering, and who are desirous of not only being well grounded in the elementals, but are anxious to keep posted on and appreciate new developments, now so far-reaching and revolutionary, are invited both to study and appropriate the instruction given, and preserve each section for future reference.

The author of this Instruction Course has had a long experience in the practical work of this highly important accessory of commercial and industrial enterprise, as well as in the art of teaching, whereby others may easily become interested and consequently informed to their profit, and we feel sure that right from the start, to express our own opinions somewhat modestly, all sections of our readers will be gratified and much benefited. The following is a brief synopsis of the course:—

Steam Engines—History, Principles, Construction, Valve Theory, Valve Setting, Steam Engine Cycle, etc.

The Bilgram, Indicator, Indicator Diagrams, etc.

Compound Engines, Condensers, Valve Gears.

Steam Boilers, Boiler Furnaces, Theory of Combustion, Smokeless Combustion, Boiler Operation.

Boiler Accessories—Pumps, Injectors, Feed Water Appliances, Exhaust Steam Heating.

Steam Turbines, Gas Engines, High-Speed Engines.

Refrigeration, Transmission, Switchboards, etc.

ENGINEERS' EXAMINATIONS.

IT is more or less surprising to note the different standards of technical and general education required by engineers' examining boards in different parts of this country. The requirements are perhaps the most stringent and thorough in the Province of British Columbia where a graded system is employed. The standards of other provinces dwindle more or less in comparison, until in some, the securing of an engineer's license is more or less a matter of form, and the appointment of examiners is left largely to political patronage.

The graded system, which makes time of service, breadth of experience and technical ability requisite steps in the ladder of advancement has much to recommend it. By means of it the employer is more likely than otherwise to secure an engineer of the necessary ability for his plant, besides being in a better position to determine meritorious promotions. The engineer has always before him the opportunity of obtaining for himself an acknowledged higher standing as an organizer and mechanic and thus making himself eligible for a higher position.

Our universities set standards at their head offices which regulate examinations for the whole Dominion, and a degree from one of them represents the same educational worth wherever it be found or by whom it be possessed. Many classes of artisans, as is the case with plumbers, etc., regulate not only the standard of remuneration, but have suceeded in securing a common standard of sanitation wherever their organizations are active, and the question of degrees of engineers' fitness is, we think, also a matter for the engineers' societies, backed up by Federal authority, to decide.

It is a significant fact that British Columbia, where the standard is comparatively high and coupled with a system of machinery inspection, has one of the most enviable records for security from machinery accidents on this continent.

ASSOCIATION AND PERSONAL

A Monthly Record of Current Association News and of Individuals Who Have Been More or Less Prominent in the Power Field.

F. W. Moore has been appointed manager of the Garlock Packing Co., Montreal branch.

W. A. Owen has been appointed city engineer of Nanaimo, B.C. The new official has been a resident of Nanaimo for some time.

Ward Curlee has been appointed city engineer of Swift Current, Sask., to succeed Geo. D. Mackie, who resigned recently. Mr. Curlee has been assistant city engineer for some time.

David Webster, chief engineer of the Brantford, Ont., waterworks, was presented by the Board of Works Commissioners, with a gold watch suitably inscribed, in recognition of his 25 years of service with the city. He was previously for 12 years with a private company which owned the plant prior to civic ownership.

R. Percy Sims, chief engineer and general manager in Canada for the Linde British Refrigeration Co., Ltd., is severing his connection with the company on May 1st, next, in order to devote his whole time to consulting work. his headquarters will be in Montreal. The Linde British Refrigeration Co. have consequently decided to close their Canadian office, as the profits of the branch have not been commensurate with those earned in other parts of the world. During the past three years the company have obtained a large number of orders from all over the Dominion; but, generally speaking, the returns obtained have been inadequate.

D. K. McLAREN DEAD.

DAVID KEAY McLAREN, president of D. K. McLaren, Ltd., Montreal, the well-known makers of high grade leather belting, died at Montreal on March 18th, after a long illness. The deceased was born in Perth, Scotland, on February 20, 1835, and was thus in his eightieth year.

Mr. McLaren had an active career and was one of Montreal's pioneer business men. He came to Canada in May, 1852, and went later to Southern Vermont, where he engaged in the boot and shoe business. In 1864, however, he returned to Montreal where he continued to reside up to the time of his death. For a great many years he was associated with other members of his family in the leather belting trade, and finally in the year 1896 set up in business for himself. In 1907 his business was incorporated as D. K. McLaren, Ltd., with the deceased gentleman as president, which position he held up to the day of his death. He had not taken an active part in the business, however, of late years owing to failing health. The firm's interests have been and still are being looked after by his two sons, W. Fred McLaren and R. M. Walker McLaren.

THE LATE D. K. McLAREN.

The late Mr. McLaren was an active member and supporter of the First Baptist Church and the Y.M.C.A. in Montreal. He is survived by a widow, two daughters, the two sons mentioned above, and by one brother, W. C. McLaren, of Guelph, Ont.

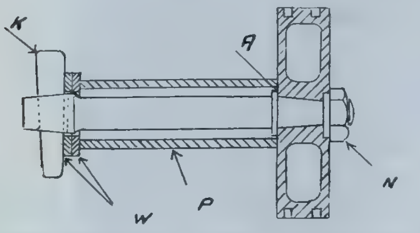
THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

REMOVING LOCOMOTIVE PISTON RODS FROM HEADS.

By R. Bell.

THE sketch is descriptive of a good method of removing piston rods from heads. These, when put on, are generally fitted up on the taper to within an ⅛ in. of the shoulder (A). The piston is then heated and the rod put in and drawn up to the shoulder by the nut (N). This makes a tight fit, and it is difficult to remove the rod again when necessary. By the method shown, a very tight piston can easily be removed. (P) is a piece of pipe of sufficient diameter to slip over the rod, and of convenient length, as shown, to come within two inches or so of the crosshead key slot. The distance between the end of the pipe and the slot can be made up with washers (W) (W) of suitable thickness, which afford a better surface for the key (K) than would the edge of the pipe. Their use also allows for a little variation in the distance between the piston head and the key slot in different rods. The washers must overlap the inner edge of the key slot so that the key will have a little draw. (K) is a tapered steel key. The pipe and washers are put on, as shown, and the key driven in with a sledge hammer. This method is much quicker and easier than heating the head when a rod has to be removed.



REMOVING LOCO PISTON RODS FROM HEADS.

FLYWHEEL QUERY SOLUTION.

By N. G. Near.

CONCERNING H. Westwood's query in the February issue of **The Power House**, there is not sufficient information given to arrive at a very exact or even satisfactory solution. Much depends upon the design of the flywheel—number and type of arms, manner of casting, bolting, etc.

Bearing "average" conditions in mind, however, I would say that there is practically no change in tension on the hub bolts. There should be none, for the same reason that there should be no change in tension in cylinder cover studs, which has recently been so thoroughly discussed in **The Power House**. Most of the stress, in flywheels, caused by centrifugal force, must be borne by the rim bolts; it having been shown, for example, that in some designs there is absolutely no change in stress in the flywheel arms save that due to the centrifugal force of the arm itself. Of course, there are bending stresses set up, caused by acceleration and deceleration, but these will be neglected here. We will consider centrifugal force stresses only.

Applying the old flywheel formula

$$P = \frac{12\,W\,V^2}{G}$$

where (P) is the tensile stress per sq. in. in the flywheel rim, (W) the weight of one cubic inch of the material of which the flywheel is made (0.26 lb for cast iron), V the velocity of the flywheel rim in ft. per sec., and G = 32.16 the acceleration due to gravity, we get, for Mr. Westwood's wheel 785 lb. per sq. in.

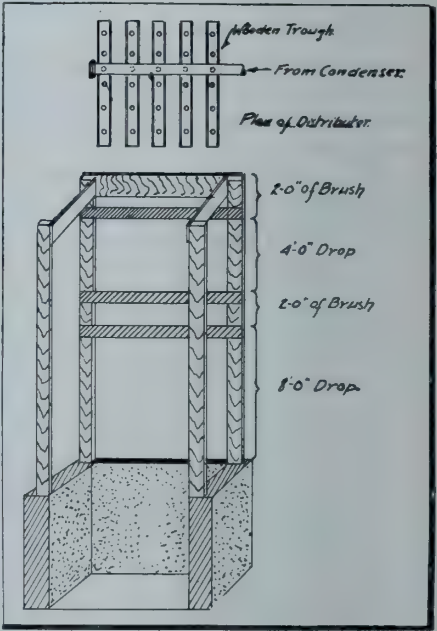
Assuming a ton to be 2,000 lbs. and, solving for the cross-sectional area of the rim, I get an area of 170 square inches. The total tension is therefore 785 lb. per sq. in. × 170 = 133, 600 pounds; the same to be held by two bolts or about 70,000 lb. per bolt, which is a whole lot more than should be allowed, inasmuch as the cross sectional area of each bolt is only about 3 sq. in., the unit stress thus being 23,000 lb. per sq. in.

I therefore contend that if Mr. Westwood's flywheel is an average design, the stress in the hub bolts will not change, whereas the stress in the rim bolts will increase about 69,000 pounds.

HOME MADE COOLING TOWER.

By Chas. Fenwick.

AMONG the attachments and accessories to a condensing engine, the cooling tower is often expensive and always more or less bulky and cumbersome. These and some other objections to the condensing engine, particularly for temporary installations have been overcome by one engineer in a very satisfactory manner. The accompanying sketch shows an improvised cooling tower consisting of a wood framework with a tank at the bottom to serve as a reservoir for the cooled water. The water from the condenser is distributed over a two-foot layer of brush or edgings by means of perforated wooden troughs as shown. From this it drops through a space of 4 feet to a second and similar layer and thence eight feet to the tank.



HOME-MADE COOLING TOWER.

The above tower has handled satisfactorily the cooling water from a jet condenser attached to a 13 in. × 30 in. Corliss engine working steadily under full load and at 20 per cent. over load for short periods. When it is desired to move the plant as in the case of portable lumber mills, etc., the water cooling apparatus can simply be discarded and a new one built.

◆

HORSE-POWER OF "ATLAS" ENGINE.

By H. W. Benton.

FRANK BAKER, Winnipeg, can very easily figure the horse-power of his Atlas engine by using the constant 4.127, thus:

Horse-power = 4.127 × M. E. P.

This constant is obtained by multiplying together the piston speed in feet per minute and the area of piston in square inches, and dividing the product by 33000, thus:

$$\frac{L\ A\ N}{33000}=\frac{\frac{16}{12}\times 268.8\times(190\times 2)}{33000}=4.127$$

It should be quite clear to all that there are three items entering into the calculaton of engine horse-power that are not variable or alterable; namely, length of engine stroke, area of piston, and horse-power standard (33000 ft. lbs.).

Now, if we have a constant speed engine we can also add that item to the list, thus: r.p.m., and there is now only one item left out, and that is the one which is always changing; namely, the m.e.p., or mean effective pressure, and all types of engine governors regulate the speed of the engine by changing this one item of the h.p. calculation. Every variation of load and of boiler pressure bring about a corresponding change in the position of the governor, and thus the m.e.p. is altered so as to just equal the power required. All Bro. Baker has to do now is to decide for himself what the m.e.p. is, and then multiply. If his full load m.e.p. be 56, then horse-power = 4.127 × 56 = 231.112, and if his friction load m.e.p. = 16, then friction load horse-power = 4.127 × 16 = 66.032. The m.e.p. can either be taken from indicator diagrams or by computing from the boiler pressure, due to point of cut-off. The procedure for this latter is, I think, too well known to need explanation here.

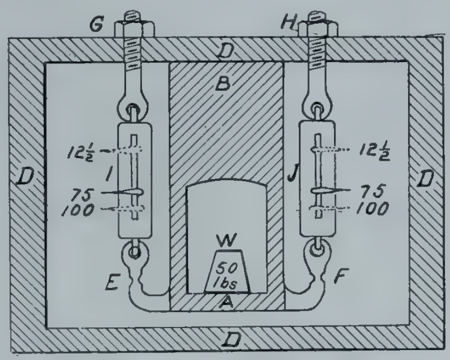
◆

TENSION ON CYLINDER COVER STUDS.

By J. G. Smith.

I HAVE read with interest the debate on "Tension on Cylinder Cover Studs," and would be pleased to see such educational discussions come up oftener in your valuable journal. I give the following as my explanation and will be much gratified if you can find space to publish it.

Referring to the sketch (AB) is a tray, containing an aperture to hold the weight (W), and arranged to press against frame (D). Supporting arms (E) and (F) are so reduced that they will break under a load of 100 pounds. These connect to the frame (D) (D) through the spring balances and bolts as shown. The weight of the tray without the weight (W) is 25 pounds. Now, if the nuts (G) and (H) be screwed up until the pointers on the spring balances register 75 pounds each, the tray (B) will be forced against the frame (D) with a pressure of 75—12½=62½×2 or 125 pounds. Upon adding the weight (W), the indications on each scale will be 12½+6½+25=100 pounds, which is the breaking load of (E) and (F).



TENSION ON CYLINDER COVER STUDS.

Supposing the pointer to have moved through a distance of 2½ inches when registering 75 pounds, the addition of the extra weight (W) will have caused (B) to recede from (D) one inch before the members (E) and (F) fail. This imaginary experiment proves to my mind that the theory advanced by Mr. Rogers is correct; that is, when steam or any other pressure is applied to a cylinder head, an immediate stress is put on the studs that support it.

◆

REPLY TO VALVE SETTING QUERY.

By H. W. Benton.

WITH regard to "Valve Setting" information required by R. W., Ottawa, it may be said that all types, styles, designs, etc., of valves and valve gears for steam engines perform the same duties; viz., admit the steam into the cylinder, cut off the steam supply so that no more can get in for the balance of that stroke, open the exhaust port so as to allow the steam to escape, and close the exhaust so as to trap a part of the exhaust for compression purposes, so that the clearance space may be partly built up in pressure by the time the live steam is again admitted for the next power stroke. These events occur as above in each end of the cylinder of a double-acting steam engine. In some types of engines these four points or events of steam distribution in each end of the cylinder are positive; that is, they take place at the same relative part of the piston stroke at all times, regardless of load, speed, or variations of boiler pressure. Such engines are regulated by throttling governors. Automatic engines do not employ any throttling device for regulation, these being regulated by varying the point of cut-off so that the quantity of steam admitted to the cylinder varies with the load and fluctuations of boiler pressure.

The simple Corliss engine is one of this class. The points of the steam distribution are positive; viz., admission, release and compression, the cut-off only being variable according to the action of the governor.

The buckeye engine, although of different construction from a Corliss engine, has exactly the same feature of regulation, the point of cut-off being the only variable.

Again, we have the Skinner engine and the Robb-Armstrong engines. These have variable cut-off and compression, and, in fact, are variable in all particulars, but the variation of admission and release is small compared with that of the cut-off and compression. These latter are controlled by the action of the governor.

The foregoing are a few pointers on valve setting in general, and although valve setting is considered by some to be a very intricate job, there is really no difficulty experienced in accurately adjusting the valves and valve gear of any type of engine after one gets thoroughly to understand the few main points.

All steam engines properly adjusted admit live steam into the cylinder while the piston is passing the dead centre; cut off the supply of the steam to the cylinder some time during the stroke of the piston, according to the type of engine, the load and the boiler pressure; release the steam from the cylinder just before the piston reaches the end of the stroke, so that the piston returns on the exhaust stroke with as little back pressure as possible; close the exhaust port just before the piston reaches the end of the exhaust stroke, so as to compress a part of the exhaust steam, thus filling the clearance space with steam at a pressure of about one-third of the boiler pressure, by the time the steam valve opens to admit live steam into the cylinder again, to repeat these four events again.

In the next issue will appear a general valve-setting article, with plain explanation of how to set the valves of some of our most popular engines.

GAS ENGINE TROUBLES.

H. Westwood.

IN the March issue of "The Power House,' on page 87, there appeared an article entitled "Gas Engine Troubles," by W. M. Grey. While I do not pretend to be an expert on this subject, I have had a fair amount of success with this kind of apparatus, and will endeavor to give my views on the cause of his troubles. The information regarding the plant being very vague, I shall have to draw my own conclusions.

There are many reasons for the engines acting as they do. One thing it is difficult to find the causes of trouble in a gas plant, because so many different things can produce the same conditions. Try only one likely cause at a time, and note the results. Don't do a half dozen things to eradicate the trouble, and having accomplished it, not know which was responsible.

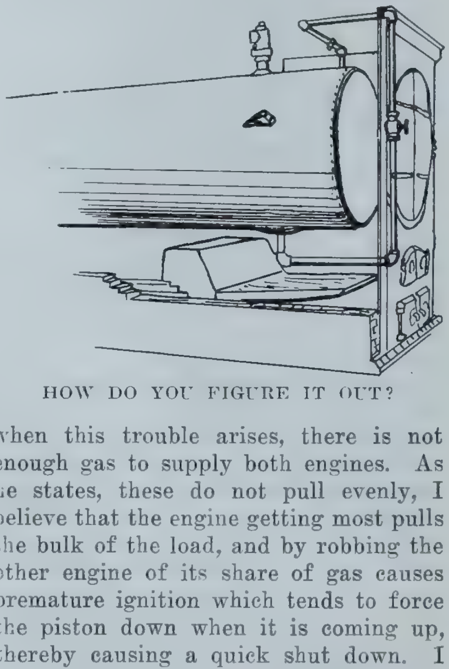
Mr. Grey states that a shortage of oil in the crank case will produce pounding. Regarding this problem of oiling, I wrote an article in the November, 1913, issue of "The Power House," on splash lubrication, which I think may be of value. I would, however, have had a better idea how to answer the query if I had known the horse-power of the engines, and the kilowatt capacity of the generators.

I do not believe that the trouble is with the electrical equipment. When two or more dynamos of different outputs, size, or make are running in parallel together, it frequently happens that all the characteristics are not exactly similar and, therefore, the load is unequally distributed, some being overloaded, while others do not take up their proper share of the work. If the difference be small, it may be compensated by means of the hand regulator, but if large, other means must be taken to cause the machines to take up their proportion of the load. If the series coils of the several dynamos are provided with small adjustable resistances in the form of German silver or copper ribbon inserted in series with the coils, the distribution of the current in the latter may be altered by varying the resistance attached to the individual coils, and thus the effect of the series coils upon the individual armatures in raising the pressure may be adjusted, and the load thus evenly divided among the machines.

If one generator were trying to motor the other it would soon become apparent by its disastrous effect, providing the circuit breaker is not equipped with a no-voltage release. Again, if the one engine were trying to pull the combined load of both machines and the other engine against full compression, it would stop the other one also. It is not stated whether the engines run with natural or producer gas of the suction or pressure system. Either one of these methods of supplying gas has its own peculiarity of making the engines behave as indicated. As either of them will close down at intervals, it is not very likely to be the fault of the magnets. My experience tells me that the trouble is with the gas.

Pounding may be due to the following causes, viz.:—Badly worn or broken piston rings, improper valve seating, a badly worn cylinder or piston, loose wrist pin in the piston, a loose journal cap, or fly wheel loose on the shaft, but none of these will stop your engine. A pound produced by any ofthe above causes is constant and will continue as long as the engine is running, but a pound caused by premature ignition may be described as a dull heavy thud which almost makes your hair stand straight. This premature ignition can be caused by three things:—poor lubricating oil, ignition too far advanced, or too weak or rich a mixture.

Mr. Grey states that he has experienced this trouble just lately. Taking it for granted that this has not always been the case, I believe he will find that when this trouble arises, there is not enough gas to supply both engines. As he states, these do not pull evenly, I believe that the engine getting most pulls the bulk of the load, and by robbing the other engine of its share of gas causes premature ignition which tends to force the piston down when it is coming up, thereby causing a quick shut down. I would advise him to pay particular attention to the suction indicators on the gas pipe or the various ones on the producer scrubber, etc., if he has one, and note the height of the suction. In a well designed plant the suction should not rise more than from three to five inches. Note also if this shut-down does not take place when the suction is high.



HOW DO YOU FIGURE IT OUT?

HOW DO YOU FIGURE IT OUT?

By Robt. McLaren.

RECENTLY on visiting a steam plant I noticed a pipe leading from the top of the boiler down the side and through the setting into the furnace. In the pipe was a valve, which the engineer occasionally opened. Curiosity led me, while the engineer was temporarily absent from the boiler-room, to open the furnace door to investigate. On the bottom of the boiler shell over the fire was a large bulge, into which the pipe was tapped.

Upon the engineer's return he opened the valve as usual and closed it. Here was an opportunity to obtain some untaxable data, so I asked him the purpose of the pipe. He said there was a "bag" on the bottom of the boiler, and that scale and mud had a tendency to settle there; so he ran a pipe from the steam space to the centre of the bulged plate, and, by opening the valve occasionally, he allowed steam to create such a disturbance that the undesirable material was driven out of the "bag" and overheating of the plate was prevented. Incidentally he remarked that the ability to achieve a desired end was more important than passing examinations for certificates.

◆

REPLY TO BOILER HORSE-POWER QUERY.

By H. W. Benton.

THE horse-power of a boiler, that is to speak strictly of boiler horse-power and not the power that can be developed by an engine from a boiler of given size, is the quantity of water that can be evaporated per hour from feed-water of a certain temperature into steam at a certain pressure.

The difference in the horse-power of a boiler at 100 lbs. per sq. in. and at 125 lbs. per sq. in. pressure is not worth consideration, so far as the boiler itself is concerned, in so far as the difference between the quantities of water it would evaporate into steam under the two different pressures from a given quantity of coal in a given time is concerned, it being so small as to be neglected.

The standard or boiler horse-power is the evaporation of 34.5 pounds of water at 212° F. into steam at the same temperature and at atmospheric pressure per hour, or its equivalent. Actual operating conditions in any plant are compared with this standard by the use of the table of factors of evaporation. Example:—

Steam pressure of 120 lbs. gauge.

Feed-water temperature at 140° F.

Quantity of feed-water per hour, say, 16100 lbs.

Factor of evaporation = 1.119.

$$\text{H.P.} = \frac{16100 \times 1.119}{34.5} = 522.2$$

In the table of factors of evaporation, the difference between 100 lbs. and 125 lbs. is only $\frac{3}{1000}$, so that the horse-power would be practically the same under both pressures.

Arithmetic for the Machinist and Workshop Operative

By J. H. Rodgers

Doubtless some of the elementary work in the first few articles of this series may appear more or less superfluous, but it must be remembered that numerous simple rules and formulae appear from time to time in Technical Journals, which are discarded and dubbed impractical by many operators for the simple reason that the elementals are either unknown or have been forgotten. The purpose of this course will have been achieved if the above tendency is even in part combatted.

INVOLUTION and evolution were explained, and the procedure to be followed in the extraction of the square root of a number was detailed in the concluding section of the lesson in our March 5 issue. In the present instance, extraction of the cube root of a number, and ratio and proportion are the features dealt with.

Cube Root.

The cube root of a number is found in this manner: Suppose we wish to cast an iron sphere which will weigh 266 lbs., what must be the diameter?

Assuming a cubic inch of iron to weigh .26 of a lb.; then 266÷.26=volume in cubic inches of the sphere=1023.077 cu. in.

To find diameter, use the formula Volume=.5236 d³, or

$$d^3 = \frac{\text{Vol.}}{.5236} = \frac{1023.077}{.5236} = 1953.928.$$

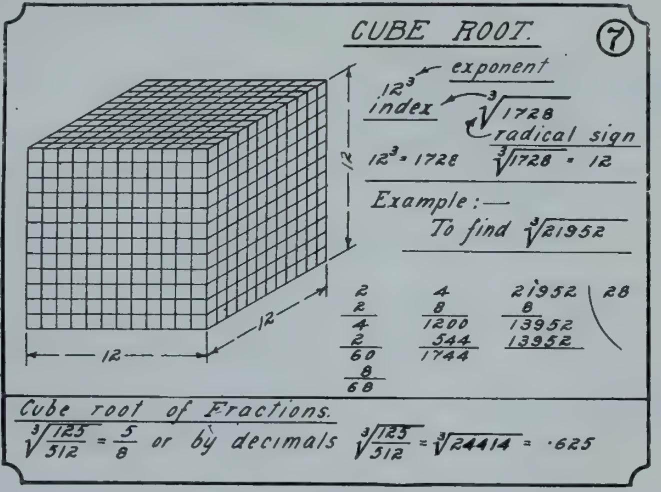
Then $d = \sqrt[3]{1953.928}$.

Explanation.—Arrange the work in three columns, placing the number whose cube root is to be extracted in the third column. From the decimal point, separate the number into periods of three figures each. Find a number whose cube is less than the first period. Write this figure as the first figure of the root, also at the head of the first column.

One	Two	Three
1	1	1953.928(12.68
1	2	1
2	300	953
1	32	664
30	332	289.928
2	68	253.176
32	40000	36.752000
5	2196	35.784832
34	42196	967168
2	2232	
360	4442800	
6	30304	
366	4473104	
6		
372		
6		
3780		
.8		
3788		

Multiply the number in the first column by the first figure of the root, and write the result in the second column. Multiply the number in the second column by the first figure of the root, subtract the product from the first period, and annex the second period to the remainder for a new dividend. Add the first figure of the root to the number in the first column for the first correction; multiply the first correction by the first figure of the root, and add the product to the number in the second column. Add the first figure of the root to the first correction to form the second correction. Annex one cipher to the second correction, and two ciphers to the last number in the second column. This is the trial divisor.

Divide the dividend by the trial divisor, to find the second figure of the root; add this to the number in the first column, multiply the sum by the second figure of the root, and add the result to the trial divisor to form the complete divisor. Multiply the complete divisor by the second figure of the root, subtract the result from the dividend, third column, and annex next period to the remainder for a new dividend. Add the second figure of the root to the first column to form the first correction; multiply the first correction by second figure of the root, and add the product to the complete divisor. Add the second figure of the root to the first correction to form the second correction. Annex one cipher to the second correction, and two ciphers to the last number in the second column to form a new trial divisor. Continue in like manner to the last period.



ARITHMETIC CHART 7.

To extract the root of a fraction, extract the required root of the numerator and denominator separately; or change to a decimal, and extract the root of the decimal. (See Chart 7.)

Consistent study of this subject will prove of much benefit to those who have been hitherto unfamiliar with its application.

* * *

Boiler Explosion.—One of the large boilers in the Bankhead plant of the Drummond colliery, Westville, N.S., operated by the Intercolonial Coal Co., exploded on April 2, and Daniel McMillan and J. Ryan were killed and five others injured.

* * *

London No. 30, C.A.S.E., annual smoker, held in their lodge rooms on April 8, proved an interesting and pleasant function. President Middleton was in the chair. An excellent programme, consisting of musical numbers and speeches, cards, and the worship of "My Lady Nicotine," contributed to the pleasure of the evening. R. Irvine, L. Sage and J. Flaven were the instrumentalists, and W. G. Walters the vocalist in the realm of music, while Geo. Moll, R. Lyons and D. F. Campbell were responsible for some speechmaking of a highly humorous order.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

Question.—A vertical steel rod, 1½ inches in diameter, has a weight of 35,340 lbs. suspended from its lower end. What is the stress per square inch of cross-section of the rod?

Answer.—Find the area of the cross-section of the rod, and divide the load by this area. Thus:

$$\text{Area} = \frac{3.1416 \times 1.5 \times 1.5}{4} = 1.767 \text{ sq. in.}$$

$$\text{Stress} = \frac{35340}{1.767} = 20{,}000 \text{ lbs. per sq. in.}$$

* * *

Question.—A hoisting drum is three feet in diameter. How many revolutions will it make in winding up 100 feet of rope. The drum is to be considered as being wide enough to take all the rope in one layer—no overlapping.

Answer.—The drum in one revolution winds up

$3.1416 \times 3 = 9.4248$ ft. of rope,

therefore, to wind up 100 feet it must make

$$\frac{100}{9.4248} = 10.6 \text{ revolutions.}$$

* * *

Question.—A locomotive has driving wheels 66 inches in diameter. If the wheels slip 22 revolutions per mile, how many revolutions do they actually make in four minutes when running at thirty miles per hour?

Answer.—At 30 miles per hour, the distance covered in four minutes is:

$$\frac{30 \times 4}{60} = 2 \text{ miles.}$$

In two miles there are 10,560 feet, and the number of revolutions made by the 66-inch (5½ feet) wheels in this distance, including slippage, is

$$\frac{10560 \text{ ft.}}{3.1416 \times 5.5 \text{ ft.}} + (2 \times 22 \text{ revs.}) = 655.18$$

revolutions.

* * *

Question.—A railroad car wheel, 42 inches in diameter, is found to be three pounds out of balance at a radius of 18 inches. What will be the "hammer blow" on the rail at every revolution when running at 30 miles per hour?

Answer.—There are 5,280 feet in one mile, and the number of revolutions made in one mile by a 42-inch (3½-feet) wheel is

$$\frac{5280}{3.1416 \times 3.5} = 480 \text{ rev. per mile.}$$

The car travels one mile in two minutes, and therefore the revolutions in one second are

$$\frac{480}{2 \times 60} = 4 \text{ revs. per second.}$$

The hammer blow on the rail will be the centrifugal force of the unbalanced weight, and this centrifugal force (F) is expressed by the formula:

$$F = \frac{Wv^2}{gR}, \text{ where}$$

F=the centrifugal force in lbs.

W=the unbalanced weight in lbs.

v=the velocity of the revolving unbalanced weight in feet per second.

R=the radius (in feet) of the path in which W travels, =1.5 feet.

g=acceleration due to gravity, =32.2.

The only one of the above factors not yet known is the volocity (v), but since the wheel makes 4 revs. per second,

$v = 3.1416 \times 3 \text{ ft.} \times 4 = 37.7$ ft. per second.

Then the hammer blow on the rail is

$$\frac{3 \times 37.7 \times 37.7}{32.2 \times 1.5} = 88.27 \text{ lbs.}$$

* * *

Question.—Find the weight of a hollow cast iron cylinder 30 inches long, 18 inches outside diameter and 14 inches inside diameter. Cast iron weighs 0.26 lbs. per cubic inch.

Answer.—To find the number of cubic inches of metal in the cylinder, subtract the inside area of the cylinder from the outside area, and multiply the result by the length of the cylinder. Take all dimensions in inches and the result will be in cubic inches. Next multiply the cubic inches by 0.26, and the answer will be the weightof the cylinder in pounds.

Area of 18 inches $= .7854 \times 18 \times 18 =$ 254.47 sq. inches.

Area of 14 inches $= .7854 \times 14 \times 14 =$ 153.93 sq. inches.

Weight of cylinder is

$(254.47 - 153.93 \times 30 \times .26 = 784.2$ lbs.

* * *

Question.—How many Imperial gallons of water are contained in a rectangular tank, 6 feet long by 4 feet wide by 8 feet deep? One Imperial gallon occupies a space of 0.16 cubic feet.

Answer.—The cubic contents of the tank are

$6 \times 4 \times 8 = 192$ cubic feet,

$$\text{therefore contents} = \frac{192}{0.16} = 1{,}200 \text{ gals.}$$

* * *

Question.—A cylindrical welded steel tank, open at the top, is made of ¼-inch plate. It has an internal diameter of 36 inches and an inside depth of 5 feet. It is filled to a depth of 50 inches with sperm oil, weighing 8.81 lbs. per gallon. Steel plate weighs 0.283 lbs. per cubic inch, and one gallon occupies a space of 277,274 cubic inches. or 0.16 cubic feet. What is the combined weight of the tank and its contents?

Answer.—Since the tank is welded, there are no rivets, lap joints or angle irons to be considered. First calculate the number of cubic inches of metal in the tank. The thickness of the tank is ¼ inch; therefore, the mean diameter is 36¼ inches, and the number of cubic inches in the vertical walls of the tank is

$3.1416 \times 36.25 \times 60 \times .25 = 1708.25$ cub. ins.

To this must be added the base of the tank, or

$.7854 \times 36.5 \times 36.5 \times 25 = 261.58$ cub. ins.

The weight of the tank is therefore

$(1708.25 + 261.58) \times .283 = 557.46$ lbs.

The space occupied by the oil is

$.7854 \times 36 \times 36 \times 50 = 50894$ cub. ins.

And the number of gallons in this space is

$$\frac{50894}{277.274} = 183.5 \text{ gals.}$$

The weight of the oil is

$183.5 \times 8.81 = 1616.63$ lbs.

Then the total weight of tank and contents is

$557.46 + 1616.63 = 2174.09$ lbs.

* * *

Question.—A stationary engineer has a cylindrical oil storage tank 24 inches inside diameter. It has a flat bottom, and on measurement he finds the depth of oil remaining in the tank to be 18⅜ inches. How many gallons of oil has he in the tank? Consult the previous question for the number of cubic inches in a gallon.

Answer.—The number of cubic inches of oil is

$.7854 \times 24 \times 24 \times 18.375 = 8312.66$ cub. ins.

Then, the number of gallons in the tank is

$$\frac{8312.66}{277.274} = 30 \text{ gals. (nearly).}$$

* * *

Question.—What weight can be raised by a single geared steam winch, of which the following are the particulars? It has two double acting steam cylinders, 8 inches diameter by 10 inches stroke; mean effective steam pressure in cylinders, 90 lbs. per sq. inch; number of revolutions per minute of engine shaft, 120; pinion on engine shaft, 16 teeth; gear wheel on winch 180 teeth; diameter of winding drum, 15 inches. The overall efficiency of the whole machine is 40 per cent.

Answer.—The horse-power developed by the engine is

$$\frac{2\times90\times.7854\times8\times8\times10\times240}{33{,}000\times12}=54.8 \text{ h.p.}$$

This is equal to 54.8×33,000=1,808,400 ft. lbs. of work per minute.

The gearing has a ratio of 16 teeth to 180 teeth; so the number of revolutions per minute made by the winding drum is

$$\frac{120\times16}{180} = 10.66 \text{ r.p.m.}$$

Therefore the load is raised at the rate of

$$\frac{3.1416\times15\times10.66}{12} = 41.86 \text{ ft. per min.}$$

By the "Principle of Work" the work put into a machine is equal to the work absorbed by the machine plus the work given out by the machine; and the work put in, as found above, is 1,808,400 ft.-lbs. per minute. We are told that the efficiency of the machine is 40 per cent. In other words 60 per cent. of the work put in is absorbed in overcoming friction, so the useful work got out of the machine is only

$$\frac{1{,}808{,}400\times40}{100} = 723{,}360 \text{ ft.lbs. per min.}$$

We have seen that the weight is raised at the rate of 41.86 feet per minute; therefore the weight which the winch can raise at this speed is the number of ft.-lbs. of work got out of the machine in one minute divided by the number of feet through which the weight is raised in the same time, or

$$\frac{723{,}360}{41.86} = 17{,}280 \text{ lbs.}=\text{weight raised}$$

* * *

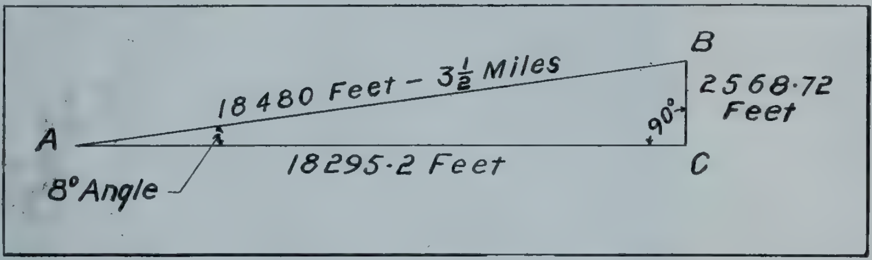
Question.—A car of 20,000 lbs. weight ascends an inclined plane of 8 degrees grade, 3½ miles long, in 15 minutes. If the friction be 3 per cent. of the load, what is the horse-power absorbed?

Answer.—Referring to the diagram herewith, let the triangle (ABC) represent the inclined plane. The angle at (A) is 8 degrees, and the distance (AB) is 3½ miles, or 18,480 feet. Now, the total work done in moving the car to the top of the incline is equal to the work done in moving it against friction through the horizontal distance (AC), plus the work done in lifting it through the vertical height (BC); consequently the first thing to do in seeking a solution is to calculate the lengths of the sides (AC) and (BC) of the triangle. Find (AC) first.

Cos. A = Cos. 8 = .99, but Cos. A $= \frac{AC}{AB}$, therefore $\frac{AC}{AB} = .99$.

AB = 18,480 feet, therefore $\frac{AC}{18{,}480} = .99$, and AC = 18,480×.99 = 18,295.2 feet.

Next find the height of the side BC, $\frac{BC}{AB}$ = Sin. A = .139, therefore $\frac{BC}{18{,}480} = .139$, or BC = 18,480 × .139 = 2,568.72 feet.



SOLUTION OF HORSE-POWER PROBLEM.

Now, the work done against friction is 3 per cent. of 20,000 lbs., or 600 lbs., moved through the distance (AC), or 18,295.2 feet, and this amount of work is equivalent to

600×18,295.2 = 10,977,120 ft.-lbs.

Again the work done in lifting the car through the height (BC) is 20,000 ×2,568.72 = 51,374,400 ft.-lbs., therefore the total work done is 10,977,120+ 51,374,400 = 62,351,520 ft.-lbs.

This amount of work is done in 15 minutes; therefore the work done in one minute is $\frac{62{,}351{,}520}{15} = 4{,}156{,}768$ ft.-lbs., and the horse-power exerted is

$$\frac{4{,}156{,}768}{33{,}000} = 126 \text{ h.p. (nearly).}$$

* * *

Question. — How long must a mild steel bar be so that, if lowered vertically into the sea, it would break with its own weight?

Answer.—Consider a cross section of 1 square inch. One foot of steel one inch square weighs 3.4008 pounds, and has a breaking strength of 60,000 lbs., and one foot of sea water one inch square weighs .4461 pounds. The net weight of 1 ft. of steel of 1 inch cross section when immersed is therefore, 2.9547 pounds, and the length necessary to produce a stress of 60,000 pounds would be $\frac{60000}{2.9547}$ or 20,318 feet.

* * *

Question.—The ram of a hydraulic elevator is 10 inches in diameter. The unbalanced weight of the elevator is 500 pounds. What hydrostatic pressure would be required to raise 2½ tons?

Answer.—Total pressure on ram is 5500 pounds. Area of ram cross section is 78.54 sq. ins., therefore 5500 pounds distributed over 78.54 sq. in. would require a pressure of $\frac{5500}{78.54} = 70.028$ lbs. per sq. in. or approximately 70 pounds per sq. in. in the receiver tank.

Question.—A Prony brake, with a lever arm 5 feet long was applied to a pulley running 275 revolutions per min. The lever was found to balance at 70 pounds on the scale pan. How much power did the brake absorb?

Answer.—Applying formula

$$\frac{2\times\frac{22}{7}\times r\times W\times N}{33{,}000} = \text{h.p. in which}$$

r = length of brake arm
W = weight on scale pan
N = r.p.m. of pulley, then

$$\frac{2\times\frac{22}{7}\times5\times70\times275}{33{,}000} = 18.66 = \text{h.p.}$$

* * *

Question.—A 48-inch cylinder is to be bored. How many revolutions per minute should the table of the mill make in order to give a cutting speed of 50 feet per minute?

Answer.—Circumference of 48-inch circle would be 48×3.1416 = 150.7968 inches, and number of revolutions required =

$$\frac{50\times12}{150.7968} = 3.97 \text{ or approx. 4 r.p.m.}$$

PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

THE SIEVERKROPP ENGINE.

THE gasoline engine here illustrated has many features of interest to users of small power units for operating cream separators, small air compressors, feed grinders, etc. It is an entirely new type of two-cycle engine.

Referring to the illustration, it will be noticed that there are two pistons (3 and 4), acting on one connecting rod (16). The tops of the two cylinders are in communication with each other by means of the passage (C). As the pistons move upwards from the position shown in the cut, they create a partial vacuum in the airtight space below. When the intake port (12) is uncovered, air rushes in, creating a suction in the fuel pipe (13). As the gasoline arrives at the end of the suction pipe in the neck of the mixer, it is immediately atomized by the passing air and becomes thoroughly mixed with it.

The two cylinders are entirely cut off from the crank case, but are connected at the bottom by a channel or passage (A). The mixture thus fills the space under both pistons and also the insides of them. It does not, however, fill the crank case. As the pistons start on the downward stroke, the mixture intake port (12) is covered by the piston (4), which traps and slightly compresses the mixture until the piston (3) uncovers the intake port in the right-hand cylinder, when the mixture at once rushes in and fills the upper ends of both cylinders.

The inrush of the new mixture into the right-hand cylinder drives before it all of the remaining burnt gases through the passage (C) into the left-hand cylinder and on out through the exhaust port, which opens just before the intake port. Immediately the pistons start on the upstroke, the intake and exhaust ports are covered, and the fresh mixture is trapped in the top of the cylinders and compressed into a very small space in the cap. Just as the pistons reach the highest point, the compressed charge is fired by the spark plug (E), and the explosion that follows drives the pistons downwards, completing the cycle.

Before the pistons reach the lowest point of their stroke, the exhaust port opens, allowing the burnt gases to escape through the muffler. The intake again opens and the new charge of mixture which has been brought in on the previous up-stroke and partially compressed under the pistons, rushes into the upper parts of the cylinders, and the same action as previously described takes place.

It will be seen that, unlike other two-cycle engines, the charge is not compressed in the crank case, where it is impossible to avoid leakage at the bearings; but is compressed entirely in the airtight chambers below the pistons.

The builders claim a very low fuel consumption for this engine, which has been put on the market to fill the needs of farmers, small machine shops, motor garages, dairies, etc. It is said to be so simple that a woman or child can operate it. It is at present being built in small sizes only—½ h.p., 1 h.p., and 1½ h.p.; but the makers are now getting out designs and patterns for higher powers. They are also working on an engine of this type for motor boats.

The Foss & Hill Machinery Co., Montreal, are sole Canadian distributors for the Sieverkropp engine.

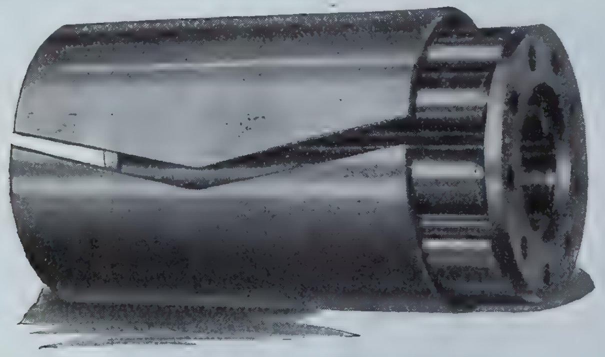
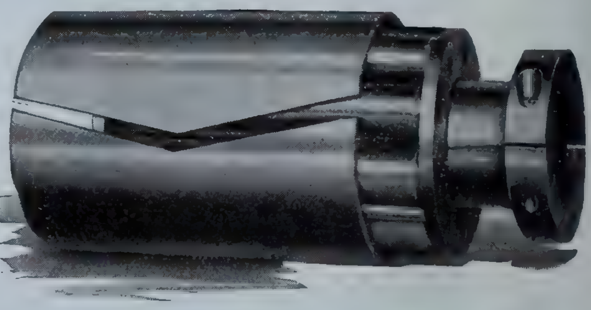
NEW LINE ROLLER BEARINGS.

A NEW and complete line of roller bearings, incorporating several new features, has recently been placed on the market for service in many forms of journal roller bearings. Every type of this line appears to bear the stamp of a careful analysis of the many conditions to be faced. A study of the accompanying illustration reveals several interesting points, chief among which seem to be ease of application, absence of roller friction, and a design that points to long bearing life.

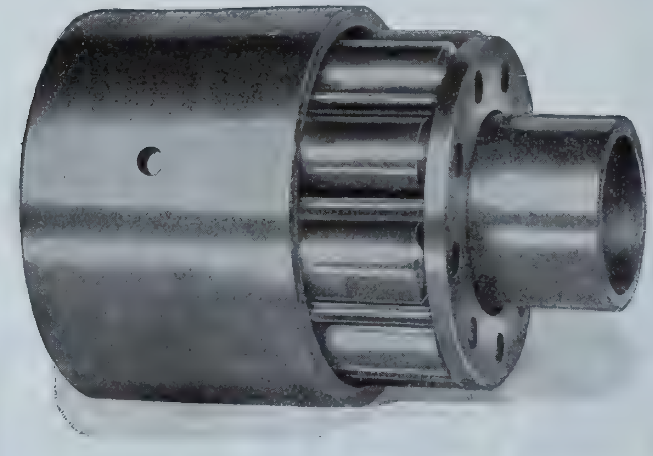


TYPE OF NEW LINE ROLLER BEARINGS.

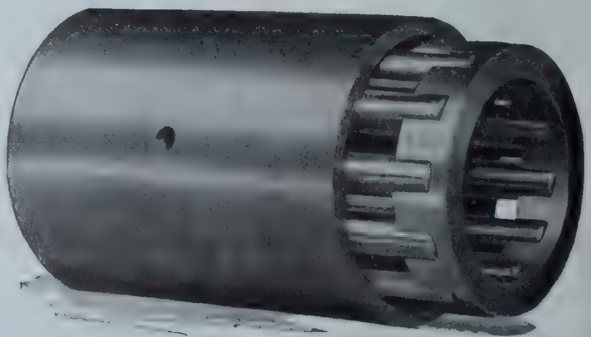


TYPE OF NEW LINE ROLLER BEARINGS.

These bearings embody the basic principles of the successful types of line-shaft bearings that the Royersford Foundry and Machine Co., Philadelphia, Pa., have been marketing for a number of years. A saving of at least twenty-five per cent. of the friction load is, we understand, guaranteed by the manufacturer, and it is reported that in many instances much higher savings have been made; which points to augmented capacity or a cheaper rate of production per machine that has been equipped. Instances are cited where a power plant which has been overloaded in driving machinery equipped with babbited bearings has run below capacity, after the substitution of these types of roller bearings.



TYPE OF NEW LINE ROLLER BEARINGS.



TYPE OF NEW LINE ROLLER BEARINGS.

The line consists of five distinct types, four of which are for use in machinery, and one in heavy wagon hubs. The first, known commercially as the "Sells Special," has a shaft-protecting feature in a split sleeve which is clamped over the shaft by two split collars. Ease of application, assurance of fit, and low-cost protection given the shaft, are advanced as prominent advantages. One of the best power-saving points in these bearings seems to be the suspension of the rollers in a permanent, revolving roller structure that keeps them constantly parallel to the shaft, and out of contact with each other; the principle being, that under such conditions, the rollers do not jamb, or become tapered; aside from the fact that their separation is said to add much to the total reduction of friction.

The entire structure is enclosed within a high-carbon steel single-piece, or "Unit Lining, which takes the action of the rollers and prevents wear of the housing. The "V" cut shown in the illustrations is to provide a diagonal joint that allows the rollers to pass over it smoothly. Another type, intended for work similar to the "Sells Special" is known as the "Sells" Commercial Type. It is actually a duplicate of the former, minus the split sleeve and collars. This bearing is said to be especially suited for journals of mine, industrial, or other light-car axles.

Two other types, designed for high-grade machinery involving heavy loads or high speeds, are the "Sells" High Duty and "Sells" Journal Bearings. They do not differ in principle, but vary somewhat in the design of the roller structures, largely because the shorter length of the former requires rollers of larger diameter to give the same capacity as the latter, with its longer rollers. Where space is not a factor, they are said to perform equally well in a given service, but where the available bearing length is limited, the high duty are recommended. They are generally used in connection with ground sleeves and casings, and for protecting the shaft and housing, when these are not specially selected for direct contact with the rollers.

◆

Boiler Explosion Finding.—The coroner's jury which has been investigating the cause of the boiler explosion at Drummond colliery, Westville, N.S., two weeks ago, which resulted in the death of five men, returned the following verdict on April 14, in the case of D. L. McMillan, one of the victims:—"That Dan L. McMillan came to his death at the Drummond colliery on April 2 by the explosion of No. 5 boiler. This jury is unable to determine the exact cause of the explosion, but from the evidence given would say that the boiler plate was not up to the standard. The jury believe that the company took all necessary precaution, but would recommend a Government inspection of all boilers."

Boiler Scale

is easy to get rid of when you KNOW HOW. A mechanical Cleaner is the only *sure way.* You may use compounds of different make, but after using them for months you will find they have failed to remove the scale and have not prevented additional accumulation.

During this experimental trial your fuel bill has been gradually increasing, and when you come to count the cost, you have paid for wasted fuel the price of several LIBERTY CLEANERS, which would have thoroughly cleaned your boilers and restored their normal capacity. LIBERTY CLEANERS are the sure way to get rid of your scale trouble. They will take out all the scale and do it quickly and economically.

One man can operate any of our Cleaners, while it requires three or more men to run a power Cleaner. If you wish to economize in your operating expenses, throw away your compounds, power Cleaners and other types of cheaply made, inefficient Cleaners and put a LIBERTY on the job.

We furnish Cleaners for every type of boiler and to be operated by water, air or steam, to suit your conditions.

"TWINS" EXCITE ADMIRATION

Because They Earn It

Think of a TWIN when you hear the word STRAINER

The installation of a Twin Strainer on your water supply line eliminates troubles, worry, waste of time and expense—because

It has two straining baskets—that may be cleaned alternately, thus permitting continuous operation.

It has but two valves—they are of the gate type and are always tight.

It gives a direct flow with minimum friction loss, insuring easy operation with no waste of energy.

In fact, a Twin Strainer is an insurance policy in active service.

Designed to protect and built to last.

Write for our bulletin.

THE TWIN STRAINER.

ELLIOTT COMPANY

Trade Gossip

Chas. Barber & Sons, Meaford, Ont., have received an order from Moirs, Ltd., Halifax, for a water turbine.

Prince Rupert, B.C.—The town has placed an order with Gerald Lomer, Ltd., Montreal, for a quantity of 18 in. and 45 in., steel piping at a cost of $86,000.

Montreal, Que. — Armstrong Whitworth Co., Montreal, have placed an order with Bruce, Peebles, Ltd., Edinburgh, Scotland, for two 350 k.w. motor converter sets.

Fraser & Chalmers of Canada, Ltd., 4 Phillips Place, Montreal, have been appointed Canadian agents for W. H. Allen, Son & Co., Bedford, England, builders of steam, hydraulic, and electrical machinery.

The Dominion Machinery Co., of 249 Victoria St., have moved their office to 82 Adelaide St. East., Toronto, where they carry a large stock of transmission equipment, also a number of hydro electric motors from 1 to 30 h.p.

Ottawa, Ont.—Owing to the increased consumption of municipal electric power and current it has been found necessary to enlarge the municipal plant on Laurier avenue. The extensions will be made this spring. The plant will be extended back as far as the canal.

The Siemens Co. of Canada, Ltd., Montreal, have received an order from the Union Carbide Co., of Welland, Ont., for some 46,000 volt single conductor cable. The cable will be paper insulated and lead covered, and will be made to withstand a test of 100,000 volts.

Siemens Co., of Canada, Ltd., have received an order for 2 and 4-core submarine cable for service between Prince Edward Island and Nova Scotia, the total length in all being 28 miles. The 2-core cable is for telephonic purposes and the 4-core cable is for telephonic and telegraphic purposes.

The General Supply Co., Winnipeg, who are Western distributers for the Beardmore Belting Co., have installed two 36-inch presses, and are now in a position to handle the belting business in proper manner. They have a large stock, and claim to have facilities unsurpassed between Toronto and Winnipeg.

Peebles Motor Converters for Canada.—Bruce Peebles & Co., of Edinburgh, Scotland, have just received the following orders for their well-known motor converters (Peebles-laCour patents):—Armstrong, Whitworth & Co., Ltd., Longueuil, Que., two 350 k.w. sets; Canada Cement Co., one 250 k.w. set. The Armstrong, Whitworth order includes various switch gear, etc.

The Siemens Co. of Canada, Ltd., Montreal, have received an order for over 700 water meters for the City of Edmonton. They will be of the vane type with frost protection. The order also comprises several compound meters with double ported valves and hydraulic balance, which is a special feature.

The Babcock & Wilcox Co. have been awarded a contract by the Brompton Pulp and Paper Co., Ltd., Sherbrooke, Que., for four 300 h.p. boilers, complete with superheaters and chain-grates. They have also received an order for three 219 h.p. boilers, steel cased, from the University of Alberta, Edmonton.

Business Absorption.—The business of the Tungstolier Co. of Canada has been taken over by the Canadian General Electric Co., Ltd., Toronto, etc. It is the intention to carry in stock a large assortment of electric fixtures for both commercial and residential lighting, and the Canadian General Electric Co. being equipped with an up-to-date fixture factory, will be able to give the very best service in this respect.

Westinghouse, Church, Kerr & Co., Montreal and New York, have been retained by the Canadian Pacific Railway as engineers to investigate the matter of the proposed electrification of the new double-track, 5½-mile Selkirk tunnel, in British Columbia. The investigations will cover in general the particular system to be installed, the relative economies of steam and water power, and the effect of the electrification upon operating conditions.

The Smart Turner Machine Co., Hamilton, Ont., have recently supplied the following equipment: The Deloro Mining and Reduction Co., Deloro, Ont., power vacuum pump; the Great Lakes Dredging Co., Port Arthur, Ont., vacuum pump; W. H. Batt, Charlottetown, P.E.I., combined air and circulating pump; the Western Construction Co., Courtright, Ont., centrifugal pump; Barfelt & Co., London, Ont., centrifugal pump; the Canada Sugar Refining Co., Montreal, duplex pump; the Goderich Lumber and Milling Co., Goderich, Ont., duplex pump; the Hinde & Dauch Paper Co., Toronto, triplex power pump.

The Turbine Equipment Co., Toronto, report recent sales as follows:—Two De Laval multi-stage motor driven pumps with capacity of 700 gallons per minute against 216 ft. head, and two De Laval single stage motor driven pumps with capacity of 600 gallons per minute against 112 ft. head., for the Canadian Copper Co., Whitson Lake water supply; one De Laval centrifugal pump with capacity of 400 gallons per minute against 70 ft. total head for J. R. Booth, Ottawa. This pump will have a motor mounted on one side and a De Laval steam turbine on the other.

The Crystal Ice Makers, Ltd., are building a plant for manufacturing artificial ice for domestic purposes, in the Ashbridges Bay industrial district, Toronto. A fifty-ton "York" ice machine will be installed as an initial unit, followed by another of the same capacity later. The machine will be installed so that it can be operated by either a steam engine or electric motor. The raw water will be purified by electricity by means of an apparatus invented by Mr. George Bury, the president of the company. It is expected that the plant will be in operation by July 1. The company is capitalized at $300,000 and has an office at 2 Toronto street, Toronto.

The York Mfg. Co., York, Pa., have recently made the following installations in Canada: R. Barron, Ltd., Toronto, Ont.; One 11-ton vertical single-acting belt-driven enclosed type refrigerating machine and high pressure side complete; O. W. Kaufman, Hagersville, Ont., one 4-ton vertical single-acting belt driven enclosed type refrigerating machine and high pressure side complete; Ryerson Bros., Ltd., Brantford, Ont., one 4-ton vertical single-acting belt driven enclosed type refrigerating machine and high pressure side complete; T. Long & Bros., Ltd., Collingwood, Ont., one 17-ton vertical single-acting belt driven enclosed type refrigerating machine and high pressure side complete; J. Y. Parkhill & Co., Ltd., Kingston, Ont., one 5-ton vertical single-acting belt driven enclosed type refrigerating machine and high pressure side complete.

Catalogues

The Dominion Machinery Co., 82 Adelaide street, east, have been appointed agents for the Frankfort furnace, manufactured by Strong, Carlisle & Hammond, Co., Cleveland, Ohio, and for the "Corona" high speed ball bearing drill, manufactured by Wright & Wood, Ltd., Halifax, Eng.

Overcoming Belt Troubles.—"How a central station can overcome its belt troubles," is the name of a pamphlet just published by the Cling-Surface Co., Buffalo, N.Y. The matter contained in its pages will prove of much value to the engineer of any central station where belts are used. The slack belt is strongly advocated. Pictures of various kinds of drives are shown and technical information is given descriptive of each drive.

The Arctic-Pownall Shell Brine Cooler is the subject of bulletin No. 5, published by the Arctic Ice Machine Company, Canton, Ohio. The bulletin ex-

Boiler Preservative

acts on the iron—not on the water. It is a boiler treatment in a class by itself.

Water treatments are only partially successful, because the scale-forming sediment in water changes with seasons, climates and localities.

"MAGIC" removes scale and oil first, and then prevents scale forming. It stops pitting, corrosion and minor leaks.

"MAGIC" saves the boiler and much labor.

A trial will convince you—write us.

NEW YORK CHICAGO

Premier Die-Stocks

Thread pipe 1 to 2 inch Right and 1 to 2 inch Left with one set of dies

Automatic Receding

Starts itself on the pipe, also automatically throws itself out after a "Briggs" Standard Thread is cut instead of backing off, which spoils the dies.

No trouble with leader screws and nuts. The new patented off-set die, which can be used **only** in the "Premier," has overcome these difficulties

No bushings to carry around or lose. The Die enables the user to accomplish, by going over the pipe once, what any other make would in going over twice.

Very easily operated.

Let us get you fully acquainted with its merits

How Much Are You Paying for Boiler Scale?

Do you know what your cost of steam production is, compared with what it costs some of your neighbors?

There are engineers who are making steam for two-thirds what it costs you. And they are doing it only because they keep their boilers free from scale with the

Dean Boiler Tube Cleaner

We would like to show you how we can help you to knock out the "scale cost" from your expense account.

Our booklet "Scale Removal Made Easy" points out the sane, safe and economical way to fight scale.

Write for it—it's free.

And ask us about our free trial offer.

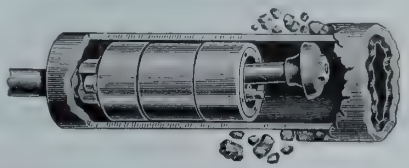
The Dean removing scale from the tube of a water tube boiler.



The Dean removing scale from the tube of a return tubular boiler.

plains the construction and operation of the "Arctic-Pownall" shell cooler and touches upon the advantages of this device for use in raw water ice-making systems. It is stated that by means of this device, the capacity of existing freezing tanks can be increased. The bulletin, which is illustrated, will be mailed to interested readers.

Heating Feed Water With Exhaust Steam is the title of Catalogue No. 51, recently issued by the National Pipe Bending Co., New Haven, Conn. The catalogue deals with heating feed water and the advantages of a closed heater, followed by a description of the "National" heater, and accompanied by several exterior and interior views showing the general construction. Tables are included, giving the dimensions and weights of the various sizes.

Ronald Trist & Co., Ltd., London, Eng., have sent us a smart-looking bulletin dealing with the "Thermo-feed" Differential Pump Governor which they manufacture. A comprehensive description is given of the governor, with special reference to its principal features, together with an excellent illustration. A leaflet containing the working details is enclosed with the bulletin. The leaflet shows a sectional view of the "Thermo-feed" Governor, each part being numbered, and its method of working described very clearly. Copies may be obtained by writing.

Oil Filtration is the title of a new catalogue which we have received from S. F. Bowser & Co., Fort Wayne, Ind. This is a very attractive publication, the reading matter being set in large type and the illustrations being colored and arranged so as to give a clear idea of the methods of operation of the "Bowser" oil filtering and circulating systems. The principal features of the "Bowser" systems are described fully, and some interesting charts are included. The latter pages are devoted to engine oiling systems, and include a diagram and several illustrations. Copies of this catalogue may be obtained from the Canadian branch, S. F. Bowser & Co., Toronto.

Book Reviews

Electric Switches for use in gaseous mines is the subject of bulletin No. 68, published by the Bureau of Mines, Department of the Interior, Washington, D.C. The main purpose of the investigations described in this bulletin was to obtain information upon which to base future tests of a similar character. The tests described were made with various types of electric switches to find out the most suitable for use in gaseous mines. Illustrations are given of the various switches tested, with a description of each switch and method of conducting the test, the results being carefully tabulated.

"Manitoba Engineer."—The 1914 number of the Manitoba Engineer, published by the Engineering Society of the University of Manitoba, has just been issued, and is a very comprehensive work. The issue contains several articles of live interest, particularly among those engaged in engineering and associated professions. The articles are well written, many of them being from the pen of men of high standing in the actual practice of engineering, architecture and surveying. The contributions are set off with numerous illustrations. The contents include the live topical questions of the day, and they are dealt with in a clear, concise and business-like manner. The article on road administration in the Province of Manitoba by A. McGillivray, Provincial Highway Commissioner, tells of the beneficial results to be derived from the construction of good roads. An article on New Manitoba and its mineral possibilities is contributed by Dr. R. C. Wallace. Street Illumination is dealt with by Prof. E. P. Fetherstonhaugh, and fireproof building construction by Thos. M. Goodrich. There are also articles on railway construction, and other topics

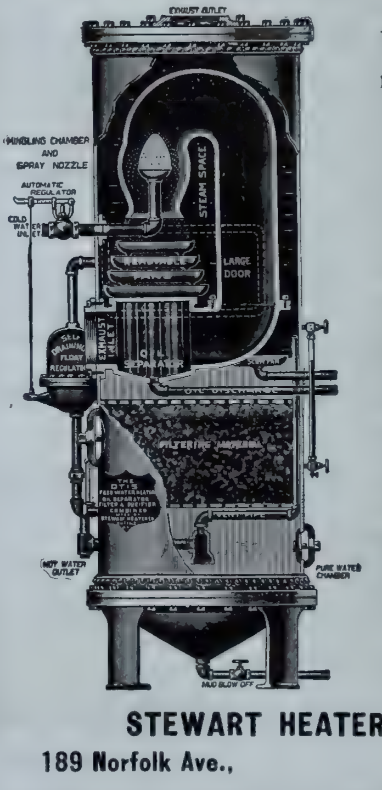
The Otis Improved Open Heater and Oil Separator with Cast Iron Pans.



This Heater is guaranteed to heat the feed water to the boiling point, 212 degrees Fahr., without any back pressure. No water can be thrown out with the exhaust steam, therefore no exhaust head will be required. Note the large cleaning door to remove the pans, also the large, deep filter and the conical bottom with blow-off pipe. Also note the cast iron float chamber containing the unsinkable copper float and brass balance regulating valve all outside of the heater and easy of access. This heater is shipped on its merits. If not found satisfactory in every respect, return at our expense. Compare with other open heaters, then note the simplicity of this. It can be used as a receiver as well.

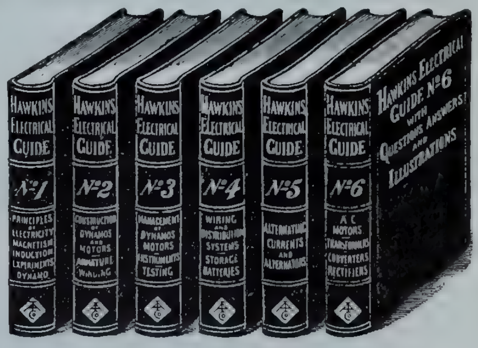
HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books
Price $1 per Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.



Hawkins Electrical Guide No 1 Principles of Electricity Magnetism Induction Experiments Dynamo
Hawkins Electrical Guide No 2 Construction of Dynamos and Motors Armature Winding
Hawkins Electrical Guide No 3 Management of Dynamos Motors Instruments Testing
Hawkins Electrical Guide No 4 Wiring and Distribution Systems Storage Batteries
Hawkins Electrical Guide No 5 Alternating Currents and Alternators
Hawkins Electrical Guide No 6 A.C. Motors Transformers Converters Rectifiers
Hawkins Electrical Guide No 6 with Questions Answers and Illustrations

"THAT'S JUST WHAT I NEED"

Read over the titles shown on the back of each volume, and note the scope of each book. They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED.

The Detroit "500" will not syphon

The Detroit "500" Air Compressor Lubricator gives constant lubrication under every condition of service. The rate of feed never varies when changing from pressure to unloading or when returning from unloading to pressure.

The Detroit "500" cannot be robbed of oil and cannot be affected by changing conditions in the cylinder.

This lubricator can be started and stopped without changing the feed adjustment, preventing both loss of time and oil when starting up.

The bullseye gauge and sight feed glasses are kept tight and won't break. This lubricator will withstand the roughest service.

HEAD OFFICE AND FACTORY **TORONTO** BRANCH FACTORIES **Winnipeg, Montreal**

It's hard work — Scurfing

Nasty, hot, uncomfortable work, too. But it's your duty, and, like a good engineer, you put duty ahead of personal likes and dislikes.

Just a moment, though! You want to try **Walker's Electric Boiler Compound** in your feed water. It will cut out all the scale, keep your boilers clean as can be, and stop your having to do any scurfing whatever.

And mind you, it won't injure them in the slightest nor interfere with the pumps in any way.

Let us send you a barrel—to try out. If it's not up to specifications return it at our expense—there'll be no charge to you whatever.

That's a pretty fair offer, isn't it?

Then write now, we have a catalog covering all our power house supplies waiting for you.

The Electric Boiler Compound

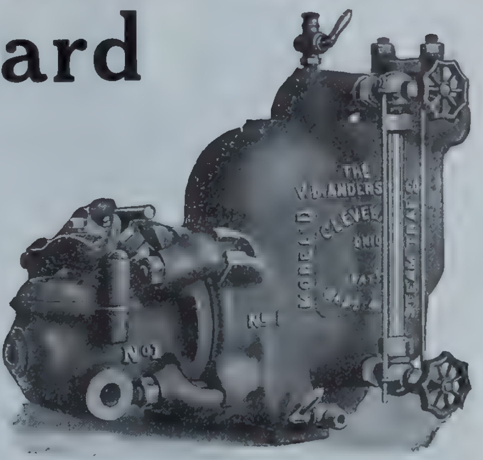
Always on guard



Unseen, unnoticed, live hot steam passes the ordinary sort of trap, and with it goes the precious heat units that you had to dig down deep into your pockets to obtain. Unseen, unnoticed, your good, real money slips away through the wasteful trap.

Think of every drip around your plant. Each one may, at this very moment be passing your hard-earned profits into the "Ewigkeit!"

How can you be sure that they're all working properly?

It's a difficult thing, all right!—that is, unless you install the

Anderson
Model "D" Steam Trap

Which will quickly let you forget steam—leaking drips, because the Anderson is ever on guard.

And it's all square and above board about it too! Its large, easily-read gauge glass gives you accurate reports as to how efficiently it is working; its quickly changed valve and seat makes the same trap fit in everywhere; its rugged and interchangeable construction makes it proof against senile decay.

Get the Booklet. It handles the Anderson, so as to convince you.

We Are Building on a Basis of Quality and Service

Users find the Bawden Pump provides the simplest, most economical and reliable means for high or low pressure pumping.

It is operated by the Bawden Patent Balanced, Steam Moved Piston Valve which insures a full stroke of the piston under all conditions.

There are no outside rods to stick or get out of adjustment.

Water valves have no screwed seats, but are driven in on a special taper and are held solid by brass stoppers through the covers, all parts made on jigs and face machined so no rubber packing is required.

PRACTICAL BOOKS FOR PRACTICAL MEN

These books were written especially for practical self-instruction, by experts whose experience and standing make them authorities.

They are so clear that the beginner can understand them; so thorough that the trained worker can learn from them; so practical that they will give any man a working knowledge of the subjects that they treat, and save him both time and money.

They not only cover the fundamental principles of mechanical science, engineering practice, and business usage, but also present the latest developments and the accepted practice of the most successful men, in those lines.

They give men a practical knowledge of practical things, which enables them to think more accurately and to work more efficiently; and they compose the most helpful, reliable, and comprehensive series of home study books ever put upon the market.

How to Charge Furnaces Economically

A very important factor in the problem of keeping a constant supply of power is that of how to stoke furnaces efficiently. We are selling agents for a system of conveying coal and for charging furnaces in boiler rooms which requires very little labor and is practically indestructible. This system consists of the well known Koppel Cast Plate Track and Charging Cars.

ORENSTEIN-ARTHUR KOPPEL

Coal Charging Cars for the conveying of coal to boiler rooms are made of steel and are very durable. They are light in weight and easy and convenient to operate, being designed with special reference to boiler room service. The height of the cars is such as to make shoveling very convenient for the stoker. They may be supplied either with two side doors or end doors, as desired, and with or without swiveling base.

The rails of the track used in our boiler room systems are cast integrally with solid sectional plates, which provide a level surface to walk upon while car is being propelled.

We have a very interesting catalogue on this subject, showing many installations of the Koppel System, together with illustrations of cars, track, switches, turntables, etc., which we should like to send you. Ask for catalogue 412.

A VERY satisfactory type of car for use in hauling ashes, dirt, etc., is the Scoop Car, which can be dumped either between the rails or to either side. Standard capacities are 12, 18 or 27 cubic feet for gauges of 18 or 24 inches.

MAGNOLIA FIXED IT

TRADE MARK TRADE MARK

East Boston, Mass., May 17th, 1912.

Gentlemen:—While Engineer of the Union Grain Elevator Company in Boston in 1891, I had opportunity of using about 100 pounds of your MAGNOLIA BABBITT METAL on a bearing of a vertical shaft, which transmitted power to three 4-foot circular grist mills which ground corn and oats into meal, and which I knew to be very hard work.

One day while all three mills were being used for grinding corn, the bearing of the vertical shaft became heated, causing the babbitt in the rear of the box to become loose and revolve around one half turn under the cap, bringing all the strain on lower step located in cellar of building, which was 25 feet below. This step, so to speak, was contained in a box of oil two inches deep, the strain being so excessive after the babbitt became disengaged, that this oil in the step reached the boiling point, which notified me that something was wrong. I immediately investigated and located the trouble. I reported same to the superintendent, requesting an immediate shut-down, which I did. He inquired of me if I could repair the damage myself (having a number of rush orders on hand), and I told him I certainly could, providing he would get me the required quantity of MAGNOLIA BABBITT METAL, which he did.

After removing all the old and inferior babbitt from the box, I re-babbitted it with your babbitt and adjusted the box in place. The shaft has run as 'cool as a cucumber' (as the saying is), not giving the slightest indication of heating, and gave the best of satisfaction.

I heartily recommend MAGNOLIA METAL to all requiring a reliable and substantial job.

Wishing you every success, I remain

Yours truly,

J. H. Clemens,
211 Maverick St.,
East Boston, Mass.

Inventors Can Use Our Machine Shop and Tools

As many inventors are desirous and capable of making their own working models, yet have not the proper machine shop equipment and facilities, we have decided to devote sections of our modern shops to this purpose.

Our buildings will be partitioned off with the necessary machines and tools, and inventors are assured of absolute privacy.

We are the only Manufacturing Patent Attorneys in Canada, and can give you every desired assistance in your work.

Write us about ANYTHING pertaining to inventions and patents.

The Patent Selling & Mfg. Agency
JAMES R. CAMERON, M.E., Manager, Suite 301-302 C.M. 22 College St., TORONTO

Ten Salesmen and Ten Salesmen PLUS—

¶ Let us take two competing firms whose lines are to all intents and purposes exactly the same.

¶ Let their policies and their service be of the same high order.

¶ And let each have *ten* salesmen of average calibre and ability.

¶ All things being equal the result of the competition is a draw. It is a tug of war with an even strain on the rope.

¶ Now let one firm become dissatisfied with this even condition of affairs. Let the idea of advertising possess it.

¶ Let the idea crystalize and publicity be added to the selling force of the progressive house.

¶ Each firm still has ten men on the road. Their individual efforts remain the same, apparently, but ten of them are now reinforced by the mightiest selling force in the modern world.

¶ One firm—the advertiser—slides ahead. The other—the stand-patter—slips behind.

¶ It is inevitable.

¶ Ten men are working under a handicap. Ten men at an advantage.

¶ The tug of war is over. It is now a case of follow the leader.

¶ If you have not already put this tremendous force of advertising behind your men you ought to, and without delay.

Rate Card and full information gladly furnished.

TORONTO OFFICE, TRADERS BANK BUILDING

Five Questions and the Answer

No. 1. Are you getting the greatest amount of efficiency out of the fuel you are burning?

No. 2. Are the interior surfaces of your Boilers coated with scale?

No. 3. Are the interior surfaces being corroded or pitted?

No. 4. Does your Engineer experience any trouble in the form of foaming or priming?

No. 5. Are your Boilers leaking around the seams and joints?

The Treatment of Boiler Feed Waters

Specified causes must be treated **specifically.** No "cure-all" will act as the proper re-agent to prevent the formation of deleterious substances under any and all conditions.

DEARBORN WATER-TREATING PREPARATIONS are scientifically prepared to meet the requirements of the mineral ingredients and other objectionable constituents of the waters used in **your** boilers, The services of the Dearborn Laboratories are offered free of charge to all power plant operators who experience difficulties due to unsatisfactory boiler-feed supplies.

Our Booklet Explains All

Write for a copy to-day. It gets right down to the root of feed water troubles, and will prove of value to any manufacturer or engineer.

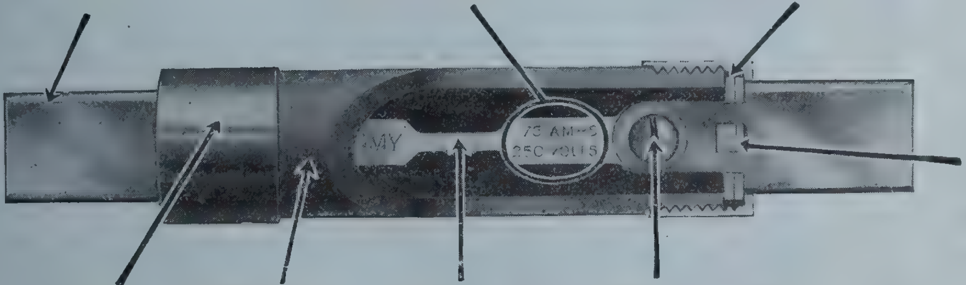
Successors to
Imperial Wire and Cable Co., Limited.

Correspondence previously addressed to the Imperial Wire & Cable Co., Limited, at 611 C.P.R. Building, Toronto, and 902 Electric Railway Chambers, Winnipeg, should now be addressed to Northern Electric Company, Limited, Simcoe St., Toronto, and 599 Henry Ave. West, Winnipeg.



Round edge hard drawn copper.

Every link stamped with name "Economy" and capacity. Guaranteed to operate as marked.

This venting feature allows no fire to escape, even on severe short circuits.

Washer assembly centres, locks in position and aligns blades.

Heavy solid brass cap.

Unusually heavy gray horn fiber shell.

Short, active length of element assures uniform performance.

Links are attached to blade member by heavy machine screws.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels. Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

Write for Bulletin Prices and Discounts

Economy Fuse & Mfg. Co. of Canada, Limited

Herald Building, Montreal

ECONOMY Renewable Fuses are sanctioned by the Canadian Fire Underwriters' Association.

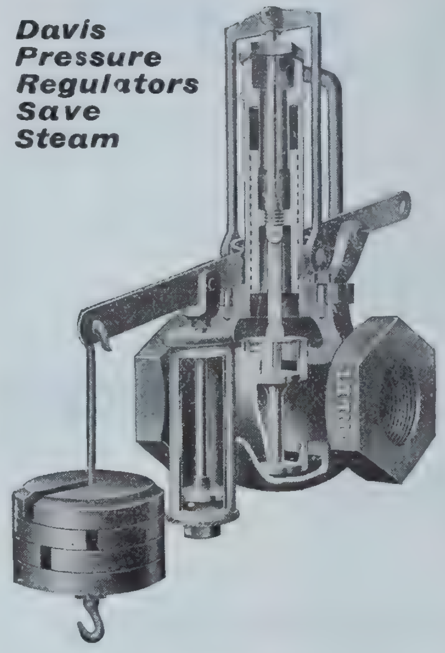
Put this valve on your steam line and forget about the pressure.

Davis Pressure Regulators Save Steam



Made in all sizes from ½ to 14-inch, with either screwed or flanged ends.

Besides the economy of the thing, there is much satisfaction in being able to get any pressure you want in your plant regardless of the boiler pressure.

No matter what the operating conditions may be, if the result you want to get is a lower pressure for a given purpose, you have at your command the

DAVIS Pressure Regulator

This automatic valve may be set for any delivery. Fluctuations in the high pressure do not affect its action, and it is good for years of service because it is very simple in construction.

All Davis Pressure Regulators are sold on approval at our risk. They must satisfy you fully or there is no sale. Let us have your inquiries.

Westinghouse

Type C Relays for Alternating Current

cover the widest possible range of application, with almost ideal operating characteristics. *All forms have the inverse time element feature.*

Overload Only—The relay alone is instantaneous at very heavy overloads, or in connection with the torque compensator gives adjustable definite minimum time at heavy overloads. This combination of inverse time element with definite minimum time is unknown in any other type of relay.

Reverse Power Only— This relay also may be either instantaneous or with definite minimum time at heavy overloads. The relay not only will not operate on power in the forward direction, but positively will operate on reverse power under the extreme conditions of voltage and power factor dropping to 2 per cent. of normal.

Overload and Reverse Power— This relay is valuable under many conditions where both features are necessary for absolute protection.

Westinghouse Torque Compensator — This device used with the type C relay modifies its characteristics so that while the relay has inverse time element at ordinary overloads, it acquires a definite minimum time element at heavy overloads or under short circuit conditions.

Torque Compensator

Type C Overload Relay

Protection of Parallel Feeders is fully provided by the use of reverse power only relays in the substation, and overload only relays in the generating station.

Protection of Series Feeders is provided by the use of overload only relays with torque compensators, thus obtaining selective action, and providing for tripping of only the breaker nearest source of trouble.

Many Special Conditions can be solved by various applications of these relays and torque compensators.

Ask for catalogue sections DS-1342 and DS-1345 covering relays and compensators.

MORRISON
BRASS VALVES

Satisfaction

Morrison Valves give satisfaction both to the Engineer and the Engineer's boss. That's what they are guaranteed to do, not for one year, but indefinitely.

The Reason

For over twenty-five years we have been making valves—studying the faults of design and material as they have appeared—correcting such faults—improving and improving till we now offer a line of brass and iron valves, up to 12 inches, which represent the most modern valve design and construction existing.

Our Line

Our line of valves includes a valve or cock for every known use. Ask us to supply a valve for any purpose—we can do it.

Our Trade-Mark

The J. M. T. trade-mark is stamped on every piece that leaves our factory, it means that the valve bearing it has withstood successfully a severe test, it means that we absolutely guarantee the material and workmanship in that valve.

Remember This!--

McEWEN ENGINES

are sold on a basis of satisfaction to the user.

They are High-Speed Automatic Engines of the best type, built to stand up to hard usage. You will find few others giving the results you can get with the McEwen when it comes to delivery power, saving steam, and standing up to the work under a varying load. Furthermore, unless we are convinced that the McEwen Engine will do your work—and do it better than another—we will not advise you to buy.

We back up every McEwen we sell with a rock-bottom guarantee that covers performance and service, and although we have sold hundreds of these engines we have never yet been asked to redeem the guarantee. The engines are built to make it unnecessary.

The McEwen Booklet is worth while—send for it.

SCREENINGS

or any grade of hard
or soft coal can be burned with excellent
results, both as regards economy and
capacity with the

"Cyclone" Shaking and Dumping Grate

68% AIR SPACE **90% UNDERDRAUGHT**

The "CYCLONE" contains an exclusive shaking feature possessed by no other Grate Bar. It means more vigorous and effective shaking, which is invaluable and can be explained by any user.

ASK THEM TO SHOW YOU THIS SPECIAL FEATURE.

The different parts of the Cyclone Grate are very strong and heavy, and few in number—and they're all protected from the heat, thus guaranteeing low repairs.

The locking device, being near the fireman's hand, keeps the Grates level all the time, so that the teeth do not stick up in the fire, and burn off.

Thirty Days' Trial

We are prepared to instal our Grates in the Plant of any reputable Company on thirty days' trial, leaving it to the purchaser to say if the Grate is, or is not, satisfactory at the end of that time. If satisfactory, we will expect payment on the terms agreed on, and if not, we will remove the Grate from the premises without cost to the purchaser.

If you wish we will put you in touch with a few users. They'll gladly tell you how the Cyclone is serving.

This Grate is imitated, but not equalled. It's to your interest to accept no so-called "just as good."

The Boiler Metal Preservative

GUARANTEE

We guarantee PEROLIN, the German Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;

2. To Prevent New scale from forming;

3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;

4. To correct troubles caused by oil and grease getting into the boiler water;

5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;

6. That **PEROLIN** is not a boiler compound for water treatment, but operates independent of water conditions;

7. The **PEROLIN** preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;

8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

The easy way to eliminate the troublesome and costly scale.

The effect of Perolin is unlike that of boiler compounds.

It works through the cracks in the scale to the boiler metal, and expands, loosening the scale so that it can be easily washed out.

It forms a **preservative film** over the tubes. This film prevents scale-forming substances from adhering, is a good transmitter of heat and prevents pitting, corrosion, etc.

We have an interesting booklet entitled, "It Doesn't Affect the Water." We'll mail it to you FREE, if you fill in and send this coupon.

SURVEYING

CHICAGO Sept. 5, 1913.

The Perolin Company of America,
1112 W. 37th St.,
Chicago, Ill.

Gentlemen:

We herewith take pleasure in submitting report on the laboratory and commercial tests on your Perolin German Metal treatment.

Distillation test and analysis of the distillate show that your product is absolutely safe to use in those plants where the live steam comes into direct contact with the manufactured products.

Corrosion tests at high tempertures and pressures on test specimens of iron and steel showed no harmful action whatsoever upon same, even when employing highly concentrated solutions of Perolin. The above tests demonstrated Perolin to have no action of a harmful nature upon boiler plate and it prevented oxidation of the test specimens.

Careful observation of tests in two Edgemoor and one B. & W. boiler, demonstrated conclusively that Perolin is an active scale remover, and an efficient scale preventative.

Respectfully submitted by

ELECTRO-MECHANICAL ENGINEERING CO.,

Gentlemen:—

I have a stock of your metal on hand, always did and will as long as I find it satisfactory as I always did.

I have used your metal on a very hard drive of shafting, and I find that it is the only metal that will keep this shaft running cool. This bearing is running now five or six years with your metal. I also used your metal on a high-speed blower that used to trouble a lot, but now that your metal is running in blower, there is no trouble. This is four years ago. Your metal is also used on a short quarter turn drive; those turns used to be iron bushings. Of course they kept me in trouble for a long time, but now that your metal is in use instead of iron, there is no trouble whatever. This is about three or four years ago. All troublesome bearings that I have had in this mill are well known to Magnolia Metal. They are doing fine.

I am

Yours, etc.,

Adrien Cote, M.M.,

Ray Mills.

Stop Blow-outs and Leaks in Pipe Lines by Using GOETZE No. 2 ELASTIC GASKETS

If you start right now to renew with No. 2 ELASTIC GASKETS, you can steadily reduce your renewals until you have brought them almost to the vanishing point.

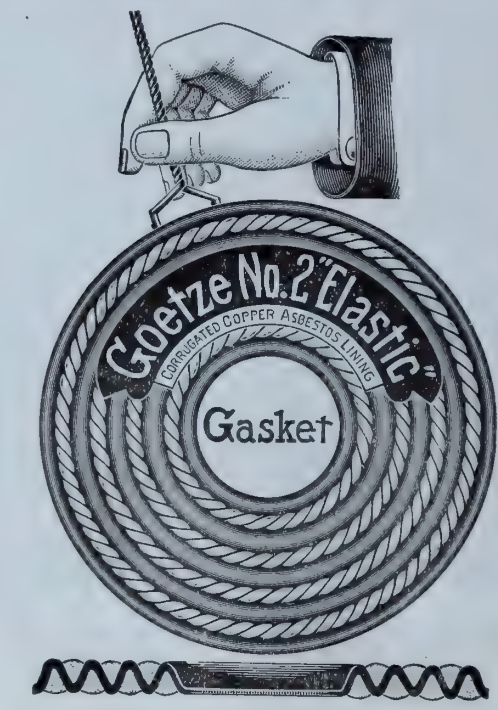
This is not a mere "claim"—it is backed up by a *guarantee*—in fact the strongest guarantee ever made by a gasket manufacturer.

Think what it means to re-gasket a joint so it will *keep tight for years,* instead of days or weeks. Think of the saving resulting in gasket costs, labor and shut-downs.

What No. 2 Elastic Gaskets Will Do

No. 2 Elastic Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight. Prevent leaks, blow outs and shut-downs. Will practically eliminate renewal expense for gaskets.

No. 2 Elastic Gaskets are for high pressure and super-heated steam lines, but owing to their indestructible nature, are equally adapted to *any and every condition* about a factory, mill or refinery.



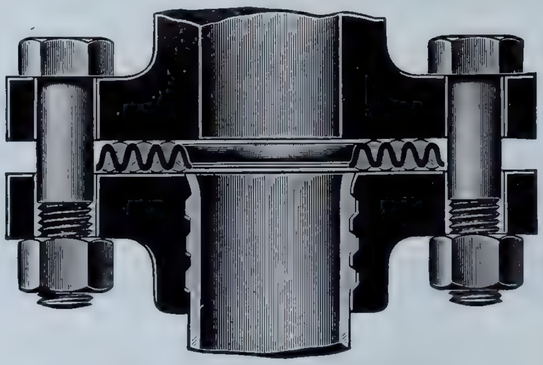
The No. 2 Elastic Guaranteed

Every No. 2 Elastic Gasket is Guaranteed for 5 Years' Continual Service in the Same Joint

There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every No. 2 Gasket whether bought direct from us or through a dealer.

How No. 2 Elastic Gaskets are Made

These Gaskets are made of corrugated copper with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.



Goetze Gaskets are carried in stock by

Don't Let This Happen To You

The menace of an "overdose" of ammonia fumes is too well realized to need emphasis—the important thing for you is to guard against any possibility of your becoming a victim.

Why take any chances so far as your AMMONIA rod packing is concerned when you can get

DANIEL'S ROD PACKING

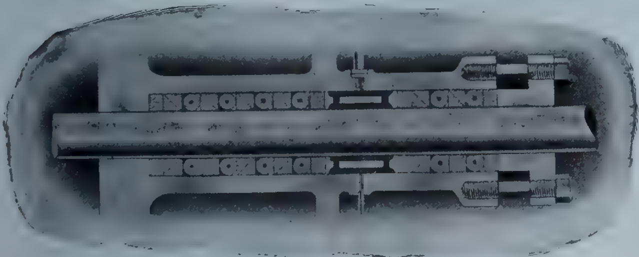
P. P. P.

FOR AMMONIA PURPOSES

The genuine Daniel's P. P. P. AMMONIA Rod Packing will positively prevent any leakage. P. P. P. will also prevent unnecessary FRICTION on the rods, with a consequent saving of power and wear. It is the trouble-saving packing for ice machines.

As the various types of ice engine stuffing boxes create such widely differing conditions that no set rule can be laid down, we advise that you write us giving make of machine, size of stuffing boxes, etc. If possible, send sketches or blue prints of the boxes.

P. P. P. for AMMONIA uses is specially prepared. Don't use your engine rod kind.



License Examination Book FREE

If you have an Ice Machine, fill out and mail the coupon to us. We will send you a FREE copy of our Blue Book of Questions and Answers to Engineers' License Examinations.

Educational Talks on Leather Belting.

Progress Made in the Manufacture of Leather Belting

In the construction of leather belts in the early days of the industry, the whole hide was cut into strips which were riveted together, so that the one grade of belting produced was made from leather that varied in quality, thickness and weight. This belting for several years answered all purposes for which belting was used.

The development of modern efficient machinery necessitated the manufacture of higher grade belting to meet the increasingly severe requirements.

Careful study in work-shop, testing-room and laboratory has resulted in the selection of hides, and the adaptation of processes and materials to produce several brands, or weights of high quality belting each peculiarly suited to certain conditions of service.

The rigid maintenance of this exact standard of quality, weight and thickness for each brand, in contrast to the old-fashioned methods mentioned above, is of vital importance, as it assures under similar conditions uniform service from any given brand of belting.

The improvement in leather for belting would have availed little had we not at the same time perfected a cement for joining laps, the use of which has superseded the old-style weak-riveted joint, and proven in actual service the strongest and most efficient method of constructing belts.

To determine the most efficient and economical quality, weight and thickness of leather belting for any particular drive it is essential to know:

First:—Whether for a horizontal drive or vertical drive.

Second:—Open drive, drive with idler, or quarter-turn drive.

Third:—Diameter of pulleys.

Fourth:—Revolutions per minute of driving pulley.

Fifth:—Horsepower to be transmitted.

Oak Tanned Leather Belting, as it has been developed, is recognized as the best belting for ordinary conditions. For certain unusual and exacting demands, however, we make a belt—our SPARTAN BRAND—using specially tanned leather and special cement—a belt remarkable for its pliability and, consequently, increased pulley grip, great tensile strength and resistance to steam, water, oil, heat and chemical fumes.

A comparison of the crude leather belting of early days, with our remarkably efficient modern product, will prove that our industry is well abreast of the day in mechanical progress.

Subject for next month : "Proper Selection of Belts."

Engineers all over the world like Cling-Surface.

Here is an example from Africa.

That Cling-Surface meets with universal approval from the tropics to the Arctics is proven by its use in foreign government service and by engineers wherever belt troubles exist. In moist tropical climates especially, where atmospheric conditions cause belts to change their length almost hourly, Cling-Surface makes fast and life-long friends. Mr. H. Jordan, a Consulting Engineer of Lorenzo Marquez, East Africa, writes us as follows:

"I have had 5 years' experience with Cling-Surface here and have recommended it with success.

"I first tried Cling-Surface on wood-working machinery, having 48 in. saws, running on 14 in. pulleys driven from 36 in. pulley on the countershaft on 20 ft. centres. I gave the belts 10 in. slack to start and had them kept clean. On account of the saw-dust I feared the slack would be too much, but they run splendidly and appear little worse for five years' wear.

"Am using a 50 h.p. gas engine driving ice-making and mining machinery. The engine pulley is 36 in., the line shaft pulley 60 in., centre distance 18 ft., and the 8 in. balata belt treated with Cling-Surface has 18 in. slack, but no slip. 26 belts on this line, ranging from 2 to 6 in., including three compressor drives, are also treated with Cling-Surface."

Operators of woodworking machinery know how difficult it is to keep the belts free from sawdust and shavings. A sticky preparation here would only make matters worse. Mr. Jordan appreciated that and used Cling-Surface because it acts from the inside of the belt to impart pliability and gripping power.

True belt economy demands Cling-Surface and the sooner you make the trial, the sooner you will realize the truth of all our claims. The cost of a trial package of Cling-Surface is insignificant in comparison with the benefits and it costs nothing unless you are satisfied. We quote f.o.b. Toronto.

Ask for literature.

A Simple Twist Tightens Any Rope

No. 95126
Hunt Tension Adjusting Coupling spliced in the rope ready to put on the drive

If one of the bands on your multiple rope drive stretches, do you resort to the old-fashioned method of cutting out a piece of rope and resplicing it?

No. 0835.
1000-H.P. Rope Drive equipped with Hunt Tension Coupling Bands.

All this is unnecessary if your drive is equipped with Hunt Tension Adjusting Coupling. A simple twist of the coupling tightens up any individual band and makes each rope do its share of the work.

If interested in learning more about these couplings and Hunt Stevedore Rope, with its unique system of internal lubrication that prevents wear and increases its efficiency, ask for a copy of our catalogue J 12.8 "Manila Rope." It contains 50 pages of information on rope drives for engineers.

At Indianapolis

THE above illustration shows an application of MORSE Silent Chains, which for compactness, reliability, efficiency and size is particularly interesting to all users of power in large units.

Read the complete details, to wit:—

1,000 Horsepower, 95 to 70 R.P.M. on 103.24″ centres. Sprockets, 61 and 83 teeth. Chain, 3″ pitch, 24″ wide. Speed, 1,450 feet per minute.

500 Horsepower, 95 to 75 R.P.M. on 135.32″ centres. Sprockets, 61 and 77 teeth. Chain, 3″ pitch, 12″ wide. Speed 1,450 feet per minute.

These chains were installed in March, 1910, for driving line shafts from engine in an Indianapolis Rubber Mill. To the best of our knowledge, neither drive has required any repairs.

Why not "Chain Your Engines Down to Duty" like this? It will pay you in power saving and increased production right from the start. Write for details, prices, and copy of Publication No. 12.

Morse Chain Company, Ithaca, N.Y. B-17 R

Since you admit that some filtering system is better than none — why not get the one that filters best?

YOU have already learned that *any* filtering system will save money and increase lubricating efficiency over none. Now consider the *most efficient* Clarifying Device.

Gravity takes out all heavier and coarser impurities, *then* each gallon of oil per hour is forced through *three square feet* of very fine filtering cloth. What impurity, what atom of grit could remain in oil so filtered? The Bowser System insures stream feed to every point to be lubricated. It returns impure oil to the filters and clarifies it. The oil is used over and over.

BOWSER
ESTABLISHED 1885

The System With Three Sq. Feet of Filtering Surface for Each Gallon of Oil

A Bowser Filter Section Extended

We broadly claim that the BOWSER SYSTEM offers the *most efficient* filtration, either as a Central Oil Clarifying System or an Individual Unit.

Surely it is worth while to investigate and learn how many are in daily use. Send the coupon for the free Bowser Book—NOW. Absolutely no obligation incurred by the request.

"AMERICAN"

STEEL SPLIT PULLEYS

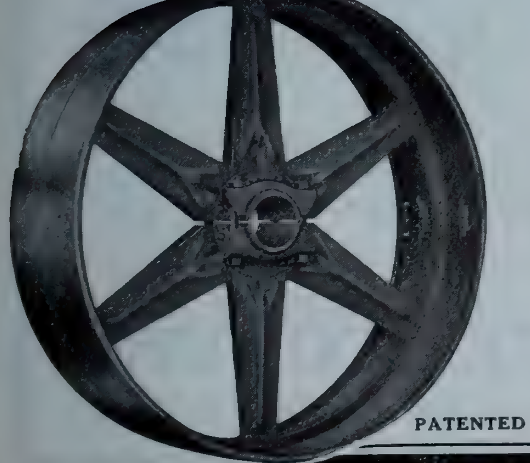
Excel In:

- Ease Of Application.
- Method Of Securing Arms To Rim.
- Safety To Belt.
- Grove In Face For Air Escape.
- Method Of Crowning.
- Saving In Air Fanned.
- Maximum Strength With Saving Of Dead Weight On Shaft.

These are most vital considerations in securing better power transmission and the importance of getting the pulley that excels in these points cannot be overestimated.

Information, concerning above and other American Pulley superiorities, is found in "Factors of Energy," a booklet containing facts and figures every pulley user should have.

"American" Steel Split Pulleys are made in diameters 3 to 60 inches inclusive. Pulleys above 60" diameter on application.



PATENTED

The American Pulley Company

Large stocks of "American" Steel Split Pulleys are carried at the following warehouses, insuring prompt shipment to customers:

Cuts Easier the Longer It Cuts.

PIPE-THREADING isn't easy, but it's been made easier by the coming of the Matchless. It's not only **easy** cutting—but it **cuts easier the longer it cuts.** Here are some of the interesting features that make the Matchless one of the most popular of

OSTER TOOLS

The Dies (one set for all sizes) are **narrow**, and **recede** as the thread is cut. This reduces labor to the **minimum**. The Dies are double taper—the first teeth do the roughing, the others the finishing. This results in **smooth, accurate** threads.

Varying the size of the dies to suit any fitting is easy. It is done by cam control and a simple setting device, requiring just one setting for each size. **Duplicate threads are made without resetting dies.**

Patented Chip Shield makes the Matchless practically indestructible. The shield protects the leader screw so perfectly that it's impossible for chips to get into the threads and injure the teeth. The coupon will bring you some interesting reading by return mail. Use it now.

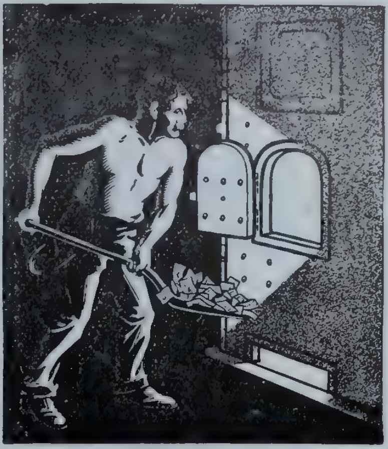
How Much Money Are You Wasting to Overcome Piston-Rod Friction?

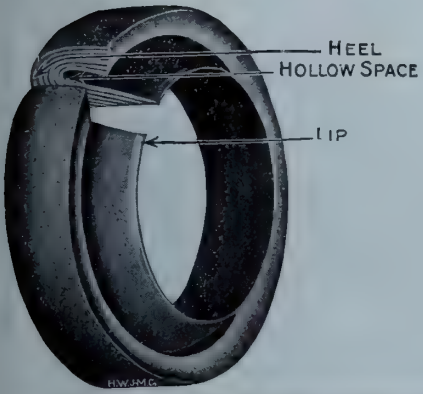


To operate the average simple high-speed 50-H. P. engine requires about 1500 lbs. of steam per hour, or 4,500,000 lbs. in a 300-day year of ten working hours a day.

As one pound of coal makes about 8 lbs. of steam, this means 280 tons of coal a year—a total annual fuel cost of $840.00 with coal at $3 per ton.

When the stuffing box of such an engine is packed with ordinary soft packing at least 5% of this power, or $42 in actual money, is wasted in overcoming rod friction! You can save at least 75% of this waste, or $31.50 in fuel, by packing your piston rods with

J-M SEA RINGS



The operation of these rings is entirely automatic. They are so constructed that their pressure against the rod is always in exact proportion to the pressure exerted on them by the steam or contents of the cylinder. In every ring there is a hollow space between the "lip" and the "heel" (see illustration) into which the steam or other gas or fluid flows, forcing the "lip" against the rod with just sufficient pressure to prevent leakage past the packing. When there is no pressure on J-M Sea Rings they do not press against the rod.

J-M Sea Rings eliminate unnecessary wear on themselves and on the rod. Therefore, they outwear ordinary rod packings.

Many other advantages of J-M Sea Rings are clearly and concisely described in our illustrated "Blue Book." Write nearest Branch to-day for a copy.

KERR

(New "KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

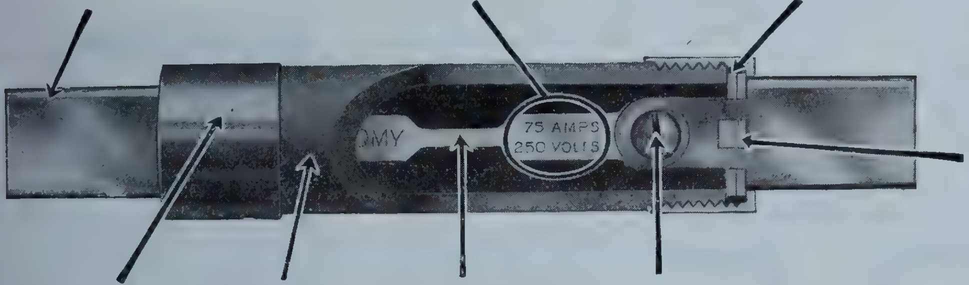
Round edge hard drawn copper.

Every link stamped with name "Economy" and capacity. Guaranteed to operate as marked.

This venting feature allows no fire to escape, even on severe short circuits.



Washer assembly centres, locks in position and aligns blades.

Heavy solid brass cap.

Unusually heavy gray horn fiber shell.

Short, active length of element assures uniform performance.

Links are attached to blade member by heavy machine screws.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

DE LA VERGNE REFRIGERATING MACHINERY

is the standard of the world in the field of refrigeration. De La Vergne machines have been installed in all parts of the world.

We have been building refrigerating machinery for thirty years and many of our machines installed over twenty years ago are to-day maintaining their high initial performance.

Our long experience in this particular work enables us to furnish the best design equipment.

We are prepared to furnish everything in the refrigerating line for Breweries, Cold Storage Plants, Packing Houses, Skating Rinks, Ice Plants (distilled or raw water systems), etc.

The name De La Vergne stands for highest quality, maximum capacity, absolute reliability and permanent economy.

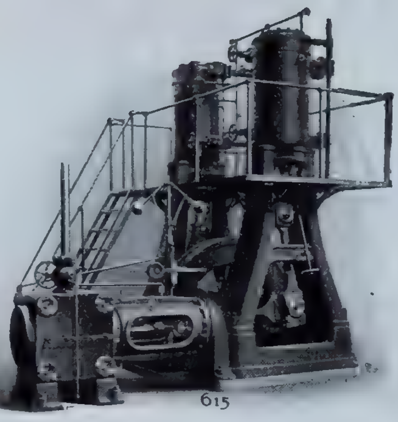
York Standard Vertical Single-Acting Machines



are the result of years of experience in building various types of Ice-Making and Refrigerating Machines.

Each Machine has built into it the best material, skill and practice at our command. It is the best Machine we know how to build. It is the Machine you ought to buy, because it can be relied upon in the rush season, when you want to crowd things a bit.

Here are some features of this Machine that should appeal to the discriminating buyer,—Wrought Steel Galleries; solid Cranks and Pins of Cast Steel; Nickel Steel Piston Rods and Wrist Pins; Cast Steel Engine Cross-head. All parts are made to jigs and templates, so that interchangeability and absolute fit of repair parts are assured. Design is simple and substantial. All parts are easy of access.

Built in various sizes from 20 to 600 tons refrigerating capacity, either belt or steam-driven, with simple or compound engines.

Write to-day for Bulletin No. 10a—just off the press—tells you all about YORK Standard Vertical Single-Acting Machines.

A Refrigerating Machine

To remain at the top of the ladder of success

Must be very heavily built;

Must have large bearings so placed as to support the engine thrust at both sides;

Must have all wearing surfaces both adjustable and renewable;

Must have large Valve areas and safety relief on discharge;

Must have every part built for service and safety;

It is by having these features and keeping them that *THE FRICK* Remains there.

THE COCHRANE STEAM-STACK HEATER

The utilization of exhaust steam offers larger opportunities for increased economies than any other field in most plants. This is because 70 to 80% of its total energy remains in the steam as it leaves the engine. The Cochrane Multiport Valve and Steam-Stack Heater are essential to the proper handling of this steam.

Where exhaust steam is used for other purposes besides heating feed water there is just one heater, the Cochrane Steam-Stack, which saves from$50 to $500 in piping and extra fittings alone over any other arrangement.

The Cochrane Steam-Stack and Cut-out Valve Heater and Receiver has an extra large oil separator capable of purifying *all* of the exhaust steam from the engines. Even when the heater is cut out for cleaning, the separator and trap remain in operation and no by-pass is required.

Results of Neglected Leakage from Boiler Joints, Etc.--I.

Through the courtesy of the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England, we are enabled to lay before our readers a record of Continental Europe practice and experience relative to defects met with by the Steam Boiler Inspection Association of Brussels, Belgium. The descriptive matter and illustrations go into minute detail, and are non-technical, making the educative feature interesting and easy of appropriation.

ALTHOUGH generally well known and perhaps more or less appreciated, it does not appear that steam boiler owners and operators realize as they should the extent and rapidity of deterioration, not to speak of the insidious approach of the danger point, else more attention would be given to the immediate investigation and stoppage of leaks from joints and other parts of their steam generation units. It seems to us that too much indifference is shown because of the apparent paltriness of the leaks when they first develop, and that so long as there is little discomfort in evidence so far as the operative staff is concerned, and no interference with the output of the manufactured product is for the time being threatened, no action to have the trouble rectified is deemed necessary. We trust that a careful perusal of this series of articles will produce a change in the above adopted attitude to steam boiler leakages. The descriptive matter, along with the sketches, show the corrosive and erosive defects liable to develop as a result of neglected leakage from joints and parts not covered by brickwork. The thickness of the plates and depths of corrosion are given in millimetres, and it may help to a better conception of the dimensions if we add that one millimetre is approximately equal to 1/25th of an inch.

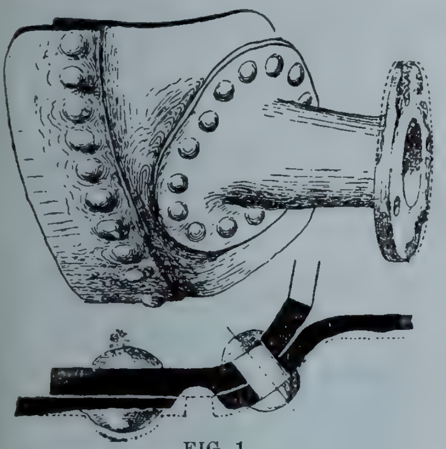

FIG. 1.

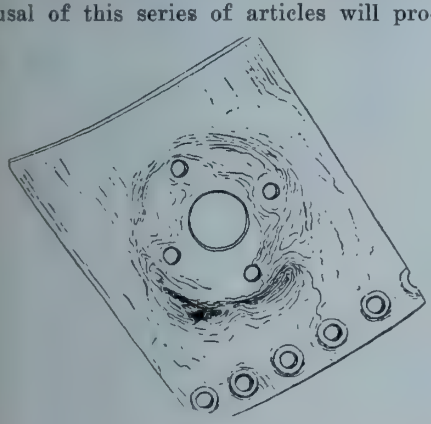

FIG. 2.

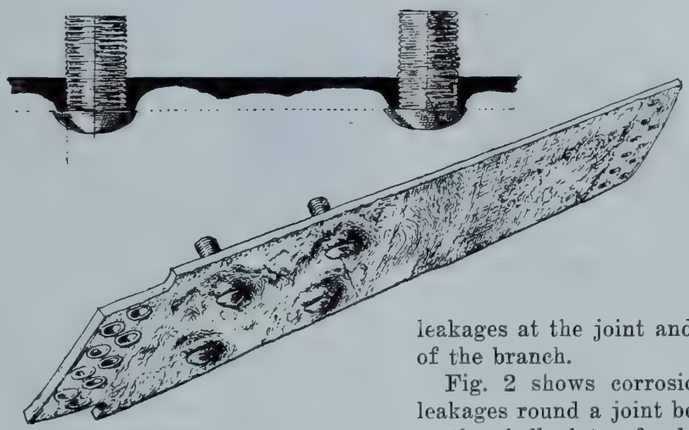

FIG. 3.

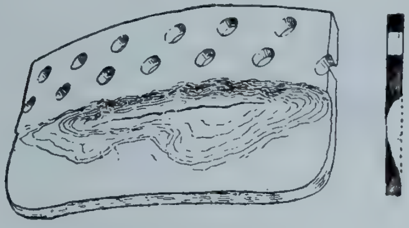

FIG. 4.

Fig. 1 shows part of the dished end of a superheater, and the report states:—

The edge of the shell ring (original thickness 9 m.m.) is corroded over a length of 490 m.m., a breadth of 60 to 100 m.m., and a depth of 2 to 5 m.m. The heads of the rivets are attacked, and the bottom of the dished end (original thickness 12 m.m.) is corroded from 2 to 5 m.m. The corrosion is most extensive near the beveled edges of the ring and of the branch, the latter being corroded generally from 2 to 4 m.m. The flange of an original thickness of 20 m.m. is also wasted, especially at the sides where the thickness is reduced to 6 m.m. The corrosion had its origin in leakages at the joint and at the riveting of the branch.

Fig. 2 shows corrosion produced by leakages round a joint bolted directly on to the shell plate of a boiler, the thickness of which was 9 m.m., and which was reduced to 2 m.m. at certain points. The corrosion in this case has only attacked one of the sides of the joints, but it extends over a breadth of 140 m.m. almost into the riveting.

Fig. 3 shows part of a marine boiler made in 1898. The original thickness of the plates was 17 m.m. Persistent leakages at the bottom of the middle circular seam have produced along the caulking and between the rivets corrosion to a depth of 7 to 8 m.m., and the whole of the part on which the water issuing from the leak has dropped is corroded. At the bottom of the front of the shell ring leakages occurred at four stays. Owing to the corrosion thus set up, a boss has been formed round each stay, and the corrosion has attained its maximum depth (9 to 10 m.m.) at some centimetres distance from the stay.

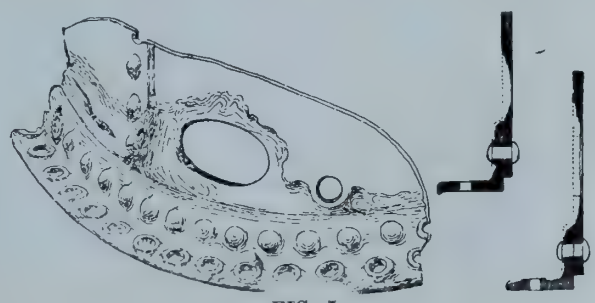

FIG. 5.

Fig. 4 also refers to a marine boiler. Corrosion at the bottom of the middle circular seam was caused by persistent leakages. The corrosion extends over a length of 400 m.m. and a breadth of 60 m.m. The thickness is reduced almost to nothing, and at the worst part the plate ultimately gave way. The original thickness was 15 m.m.

Fig. 5 shows the bottom of the shell of a small vertical boiler. Leakages at the riveting of the angle iron and at the joint of the wash-out opening have produced severe corrosion. The thickness of the horizontal plate of the angle iron is reduced in places at the edge to 5 or 6 m.m. The rivets in this part are now headless. The vertical plate is corroded from 3 to 4 m.m., and the rivets have scarcely any head left. Along the caulking of the angle iron at a height of 4 to 5 m.m. there exists a deep blotch of corrosion, and the thickness there is reduced in places to 2 or 3 m.m. (original thickness 13 m.m.). Around the door of the wash-out opening, particularly at the higher part, there is corrosion 20 to 30 m.m. in breadth. The remaining thickness of the plate is only 5 to 6 m.m.

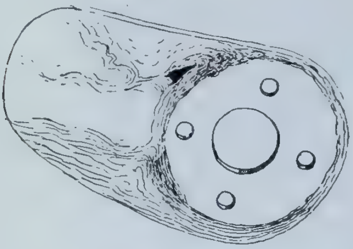

FIG. 6.

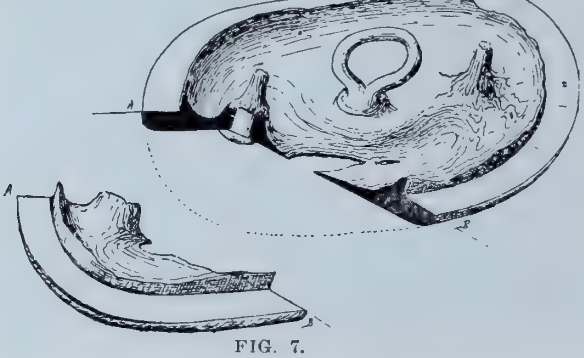

FIG. 7.

Fig. 6 indicates corrosion round a joint bolted on to a plate of 10 m.m. thickness. The grooving is 15 to 20 m.m. in breadth and 4 to 10 m.m. deep. At one point the plate has worn through into a hole, while, in addition, the leakage has caused two grooves 3 to 4 m.m. in depth to spread around the joint.

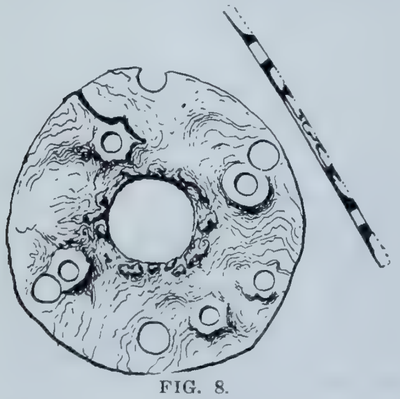

FIG. 8.

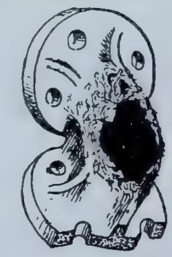

FIG. 9.

Fig. 7 is that of a cast iron manhole cover 25 m.m. thick. Leakage round the joint have almost eaten away the thickness of the projecting part intended to preserve the joint. The two attaching bolts of an original diameter of about 30 m.m. have been reduced to 12 m.m. In the middle there is severe corrosion, which at one point has eaten through the cover.

Fig. 8 shows the flange of a pipe corroded by leakage at the joint and round the bolts. The thickness of 11 m.m. is in places reduced to nothing, while at three of the bolt holes the portion of the plate which was covered by the nut is intact.

Fig. 9 refers to a cast iron blow-off elbow, of which the thickness is reduced to nothing by leakage at the joint. The pipe was found partly covered with dust and ash, which the leak kept in a damp condition.

Fig. 10 is that of a covering plate at the bottom of the front end plate of a boiler with internal furnaces. The bottom of the front end plate is very little above the level of the stokehole floor, and is frequently covered with ashes. Leakages from the manhole and ashes have caused very rapid corrosion of this plate, which was originally 20 m.m. thick. The corrosion commenced in the riveting of the stiffening ring of the hole, and in the bottom flange the thickness has been reduced to nothing over a space of about 500 m.m. On the same area, the rivets of the first circular shell seam are practically headless. Starting from this point, the corrosion gradually diminishes, and in the back part of the seam it is scarcely more than 2 to 3 m.m. in depth.

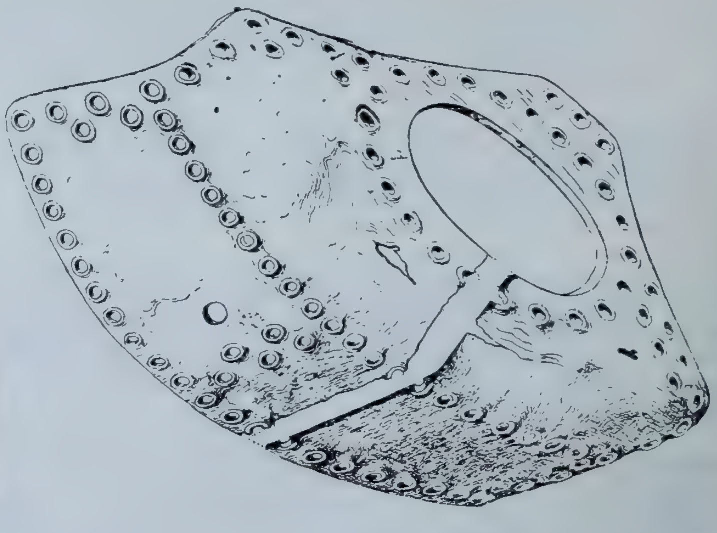

FIG. 10.

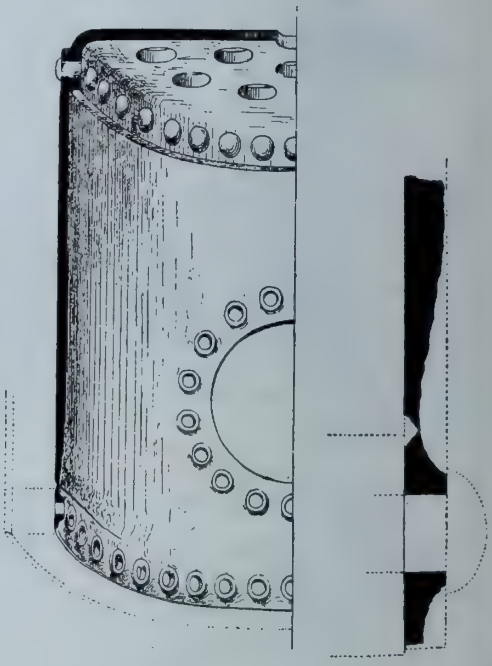

FIG. 11.

Fig. 11 refers to the bottom of the firebox of a small vertical boiler with smoke tubes. On the water side at the level of the foundation ring there are two grooves caused by corrosion, one covering a space of 400 and the other 300 m.m. These grooves are in parts 10 to

12 m.m. in breadth and 5 to 6 m.m. thick. On the fire side the bottom of the firebox is much corroded in and under the riveting, probably owing to the presence of ashes kept in a damp state by leakages at the riveting. In certain parts the edge of the plate has been reduced to between 5 and 6 m.m. in thickness. Many rivets are practically headless. Over a space of about 150 m.m. the plate is fractured at a place where the thickness has been reduced to nothing owing to the effects of internal and external corrosion at the same point.

DESIGN AND STRENGTH OF WORM GEARING.

By A. Best.

MUCH has been said at the meetings of our engineering societies, and much has been written in journals and text-books on the subject of gear strengths, but one may still look in vain for a simple solution to the problem of what power a given worm gear will safely transmit.

All gearing should be designed with a fair factor of safety, and in most cases now the size of the gear is more or less determined by the nature of the load: whether subject to shock or fairly steady. Another influential factor is the length of life expected from the gears. These conditions naturally cause the designer to get well beyond the point of destruction. It is found then that gears are really designed for wear, and it is, therefore, desirable to watch those points which, though they do not seriously increase the weight or cost of the gears, allow more accurate meshing. The consequences are—smoother running and longer life.

It may, perhaps, be imagined that by using a greater width of wheel face, an increased power can be taken through the gears. This is true only to a limited extent, because as the wheel gets wider, the diameter of the pitch surface at the sides of the teeth gets greater, and as a consequence the pitch is greater. When this increase is very great, the gears cannot mesh properly at those points, and inaccurate meshing, owing to the wheel teeth getting out of pitch, causes considerable friction and rapid wear. This fault often causes the excessive generation of heat. Gears overheated can frequently be remedied by reducing the angle of throat. When this throat angle is not allowed to exceed 70 degs., then the increase in pitch is not sufficient to seriously impair the working of the gears.

Another point to watch is the length of the worm, and if the latter be made of such a length that the ends are clear of the outside diameter of the wheel (at the bottom of the throat radius), there will be no fear of the rattle which is sometimes heard, when the ends of the worm threads strike suddenly into the wheel teeth instead of smoothly sliding into mesh. It has been said that this worm is too long—owing to the law that no tooth contacts can take place out of the line of action. This is all very well for a new pair of gears, but when wear has taken place, matters are slightly altered.

Chart Feature.

With regard to the strength of worm gears, the accompanying chart will serve to solve this problem for bronze worm wheels. Bronze wheels give the most satisfactory results—either solid bronze gears, or cut bronze rings shrunk on cast-iron centres.

To use the chart it is first necessary to assume any worm and wheel to give the reduction required, then proceed to find by the chart if the assumed gear is suitable for the power which it is intended to transmit. If not, the pitch or pitch-line diameter of the worm should be altered until the required power is obtained.

Next calculate the pitch-line velocity of the worm wheel as follows:—

$$\frac{\text{Pitch ins.} \times \text{No. teeth} \times \text{revs. per 10 in.}}{12}$$

=Pitch line velocity in feet per min.

Then find the position on the axis (L M) for the value obtained. Follow this horizontally to the curve in graph (A), down the corresponding ordinate and cross axis (L K) to the line in graph (B), marked with the linear pitch of the worm. Proceed horizontally across (K N) to the line in graph (C), representing the pitch-line diameter of the worm used. The point on the axis (N P) vertically under this will give the horse-power for which the gears are suitable. The method is based on the proposals put forward in this article, and will be found ready and reliable.—Page's Weekly.

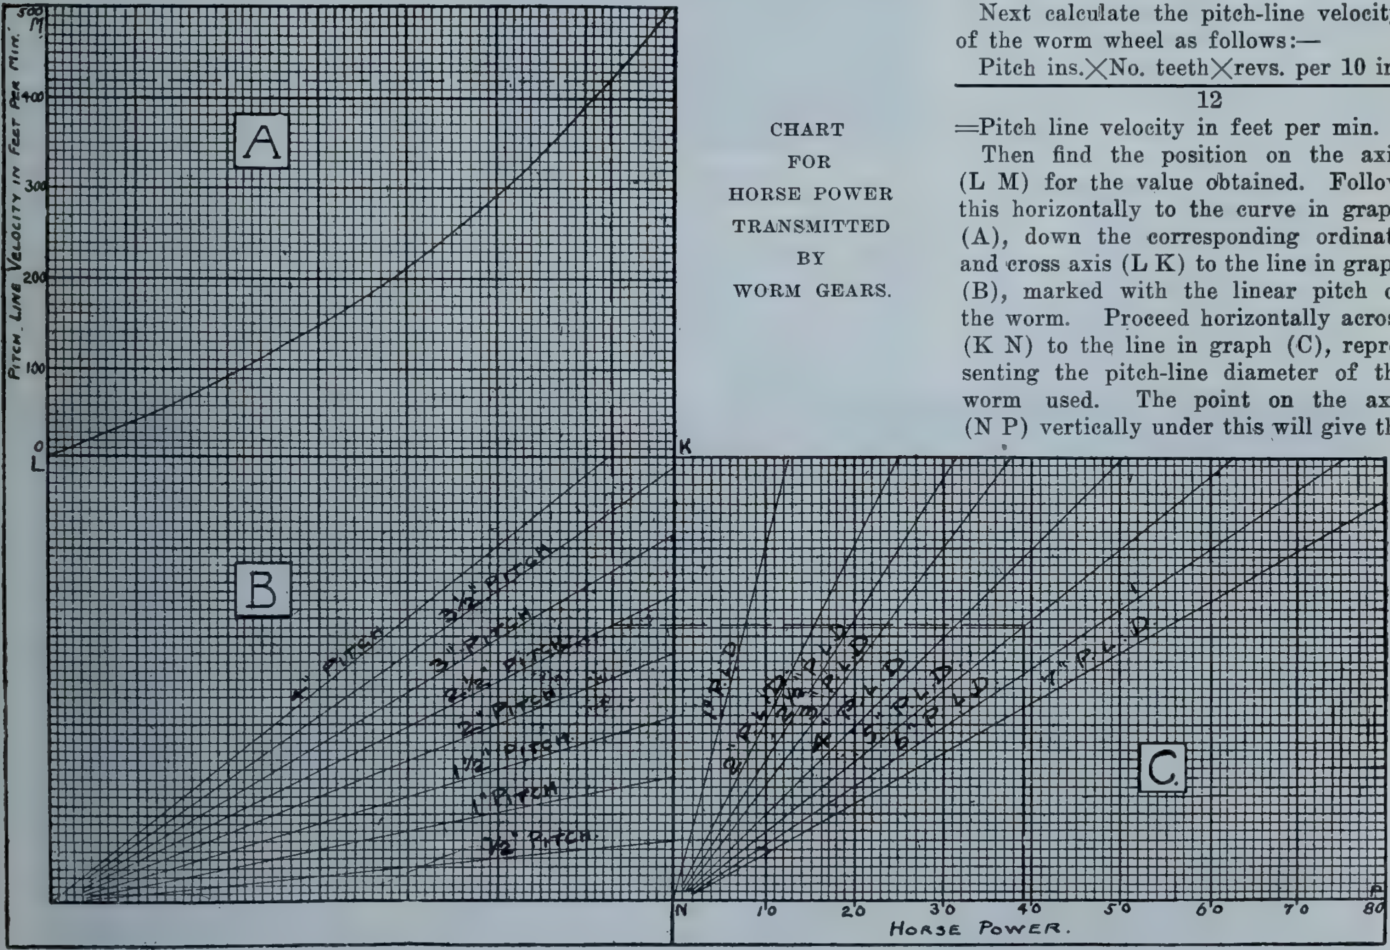

CHART FOR HORSE POWER TRANSMITTED BY WORM GEARS.

Description of a Testing Plant for Centrifugal Pumps

A testing plant for centrifugal pumps has been built at the works of Canadian Allis-Chalmers, Ltd., Rockfield, near Montreal, which can be reckoned, without fear of contradiction, we believe, as one of the best equipped and most up-to-date hydraulic laboratories on this continent.

A CENTRIFUGAL or turbine pump is not a positive displacement pump and there are no "rule of thumb" methods of arriving even approximately at its capacity. It may be accepted then that a well-equipped testing plant is one of the most important essentials for the successful manufacture of centrifugal pumps.

From the manufacturer's standpoint the records of tests carefully carried out are of the utmost value, as they constitute the foundation upon which future propositions can be based, designs developed, improved and modified to suit particular requirements. From the purchaser's standpoint, on the other hand, is the absolute assurance that the hydraulic and efficiency requirements have been fulfilled and, secondly, that a trial run of several hours' duration will insure continuous operation of the machine with no mechanical difficulties arising after leaving the works.

There are a number of testing methods in use with varying degrees of accuracy, and they may be classified as follows:

(a)—Weight or volume method.
(b)—Weir method.
(c)—Velocity meters.

The last group includes Venturi meters, nozzles and the Pitot tube.

The instruments required, pressure and vacuum gauges to determine the total head; watt meters to determine input to motor, or indicator to determine horse-power of steam engines, have long been standardized and are usually accepted without question by consulting engineers and representatives of purchasers on official tests; in any case their calibration is a simple matter and facilities are provided for this purpose at the Rockfield Works. The measurement of the quantity of water being handled, however, presents many difficulties, because the methods generally adopted, owing to their cheapness, such as weirs, nozzles, pitot tubes and, in fact, all velocity meters, are open to the very strong objection that their accuracy depends on constants determined by experiment which, as far as consulting engineer or official representative is concerned, may or may not be right. A means of direct measurement either by weight or volume is an absolute necessity.

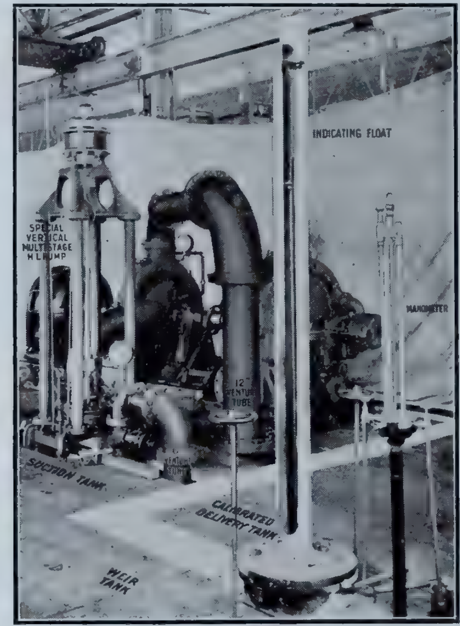

Fig. 2. CLOSE VIEW OF MANOMETER AND FLOAT.

Test Plant Details.

In the testing plant at the Rockfield Works, no one single testing method has been relied upon, but any one of the three above-mentioned testing methods can be used and the volume method can be used to check either the Venturi meters or the weir. It may be stated here that a testing plant established at the Mather & Platt Works, in Manchester, England, whose well-known centrifugal pumps, Canadian Allis-Chalmers, Ltd., have successfully manufactured for several years, served as a basis for the design of this unique equipment.

Figs. 1 and 2 represent general views of the testing plant and, referring to Fig. 3, the overall dimensions of the tanks alone, which are 34 ft. 6 inches long, 18 ft. 3 inches wide and 9 ft. 4

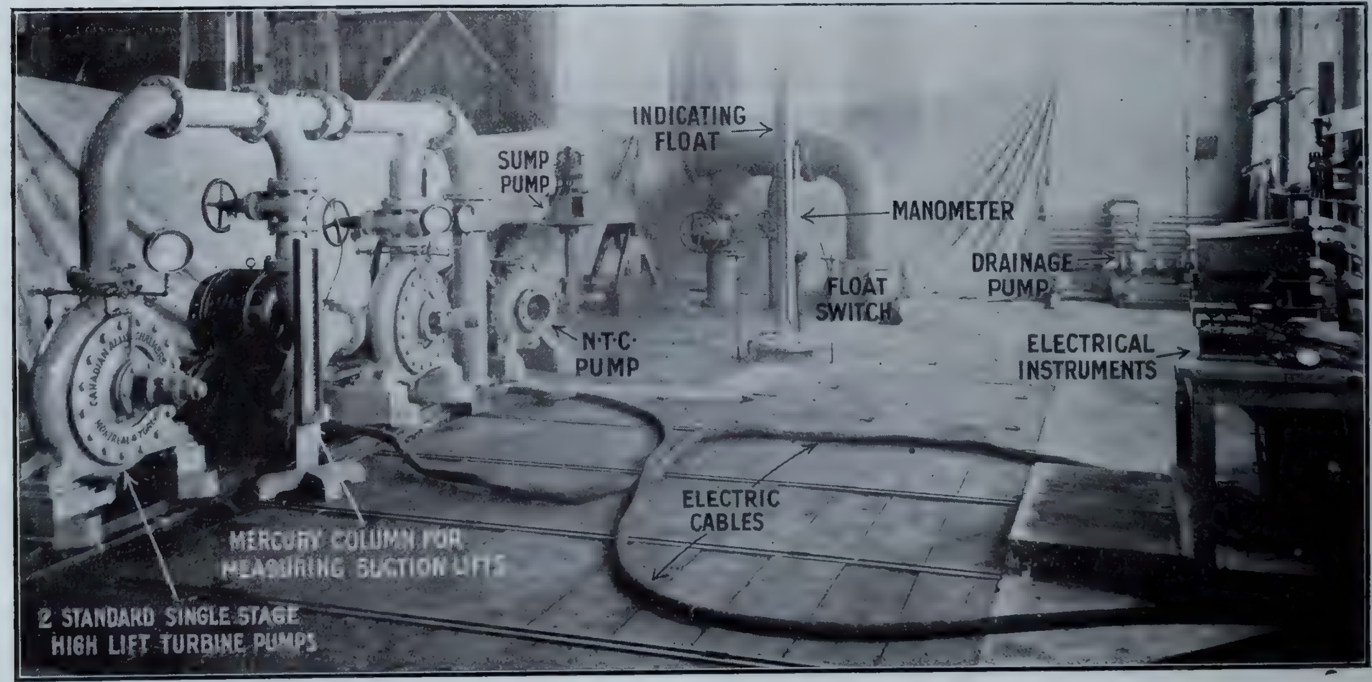

FIG. 1. GENERAL VIEW OF CENTRIFUGAL PUMP TESTING PLANT.

inches deep, will satisfy the reader that an equipment of such proportions is well able to cope with the largest pumping units. It can be seen that all tanks have been placed underground so that factory space is not wasted and the flooring made in such a way that the tanks can be easily uncovered. The total area has been divided into three tanks. The suction tank is 18 ft. 3 inches long, 15 ft. wide, 9 ft. 4 inches deep. The calibrated delivery tank is 18 ft. long, 11 ft. wide, 7 ft. 4 inches deep, and the weir tank is 18 ft. long, 5 ft. 9 inches wide by 7 ft. 4 inches deep.

All tank walls are made of waterproofed concrete and the bottoms carefully leveled. By raising the bottom levels of delivery and weir tanks above the suction tank, they drain by gravity through connecting valves into the suction tank. A small motor-driven centrifugal pump, which can be seen in the right-hand corner of Fig. 1, serves as drainage pump for all tanks. Suction pipes with foot valves and strainers of various sizes may be noted in the suction tank, and little time is lost in making the suction pipe connections when pumps about to be tested are bolted to the cross rails, thus providing a firm setting-up.

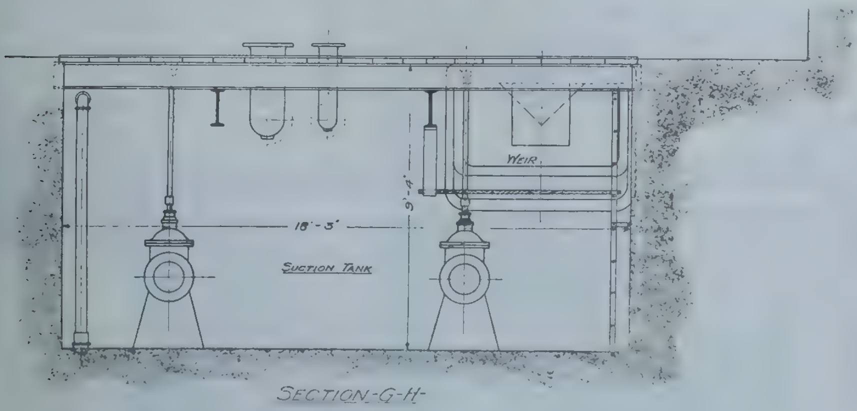

FIG. 4. CROSS SECTION OF SUCTION TANK.

The discharge connections are formed by two elbows, a 6-inch and 12-inch which connect to a 6-inch and a 12-inch Venturi meter respectively. Following the discharge pipes, they are carried to a common large pipe, which finally connects with a water switch, the function of which will be described later. By removing a blank flange, a passage can be made from the delivery tank to the weir tank. On the wall dividing the delivery tank from the weir tank can be seen a Manometer which, by means of pipe connections to the Venturi meter tubes, registers the amount of water flowing through the tubes. Next to this instrument is mounted a float with indicator which shows the height of water in either delivery or weir tanks by opening and closing valves.

Referring to the weir tank, the cast iron weir frame may be noted which is set in the wall dividing the weir tank from the suction tank. Weirs of the V-notch shape, and rectangular weirs of 18, 22, 24, 35 and 48-inch widths can be inserted in this frame. A ladder with a platform has been provided to allow the test operator to descend and observe the leveling and careful setting of the weir crest to the zero mark of the float scale. Baffle plates in the weir tanks can be raised or lowered in wall frames to best advantage to check any disturbances of the water and to insure a quiet flow near the weir. A table with the necessary electrical instruments to measure the

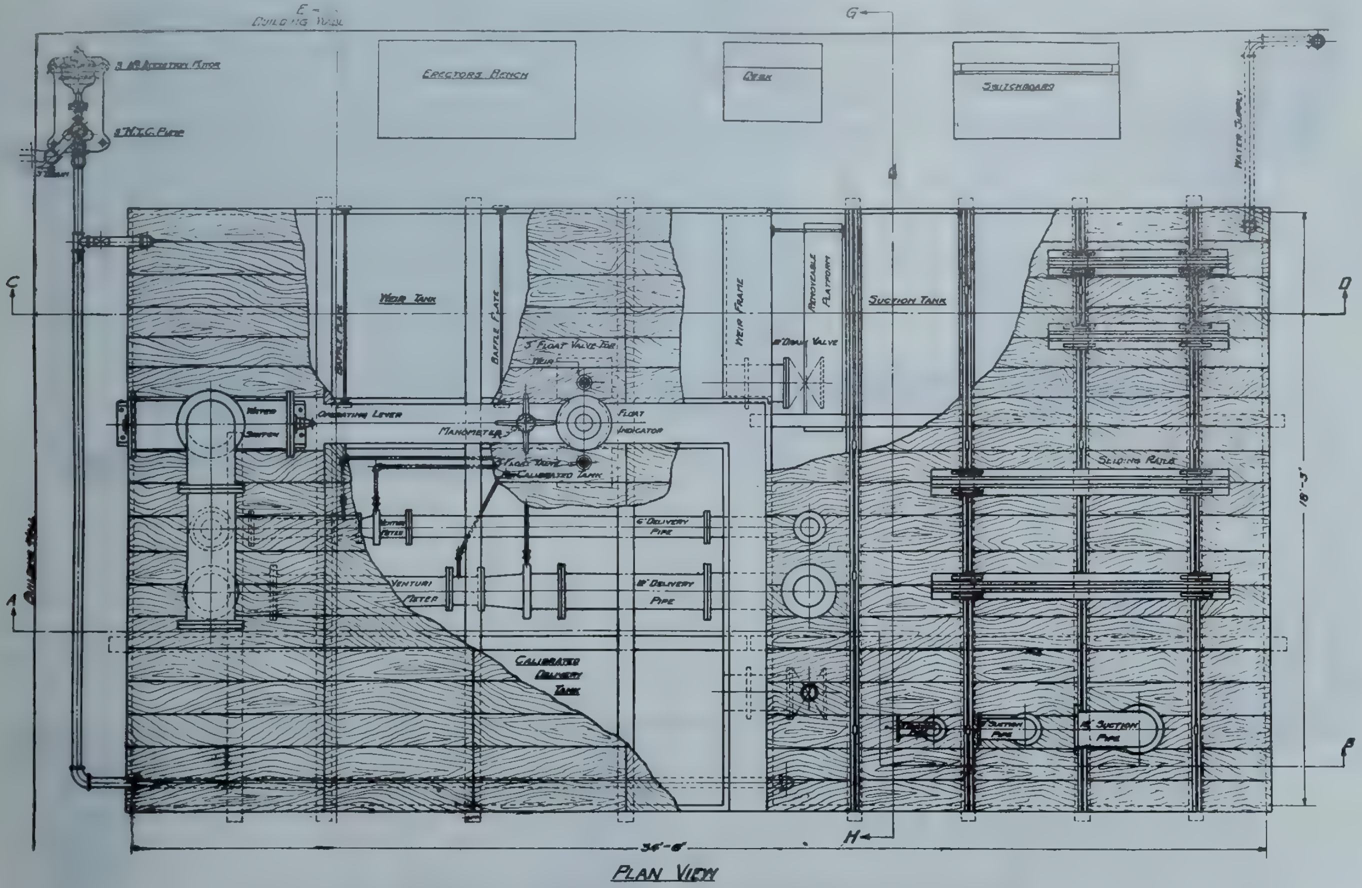

FIG. 3. PLAN OF TANKS SHOWING LAYOUT OF METERS AND PIPING.

electrical input, and engineer's desk and a fitter's bench complete the equipment.

Method of Test.

The method of test is as follows: All suction pipe connections are made with the above-mentioned pipes in the suction tank. The discharge connection is made with one of the two elbows, according to the size of pumps to be tested, and the water is discharged direct into the water switch. By operating the hand lever, the water can be instantaneously switched either into the calibrated delivery tank, or into the weir flume. As the name indicates, the delivery tank, although of uniform section, has been carefully calibrated by weighing the water and noting the rise of level on the float scale. Assuming that the operator by means of the water switch has directed the flow into the weir flume, he next observes the weir flume scale on the float and the manometer reading at the same time, thus checking the weir against the Venturi meter. The float is now closed to the weir tank and opened to the delivery tank. The level of the water in the delivery tank having been observed and, with stop-watch in hand, he throws over the water switch lever, allowing the water to fill up the delivery tank.

The operator allows the pump to discharge into the delivery tank for from say one minute in the case of ten thousand gallons per minute pumps to even half an hour if required for five hundred gallons per minute pumps, and noting the time, switches the discharge from the pump back into the weir flume whence it continues to circulate round. At his leisure, and when the water in the delivery tank is quite still, the operator observes the new level and, subtracting

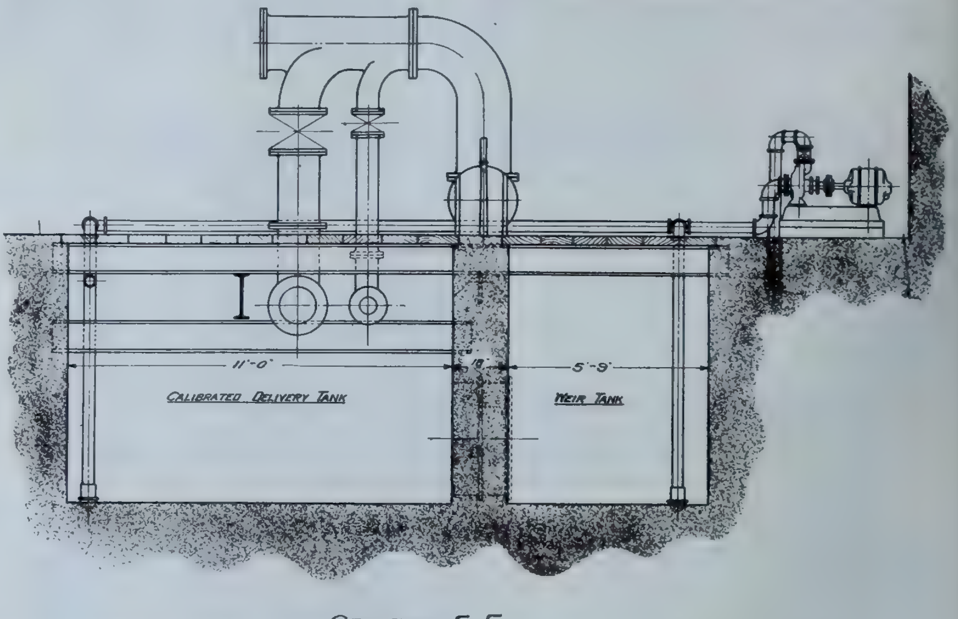

FIG. 6. CROSS SECTION OF DELIVERY AND WEIR TANKS.

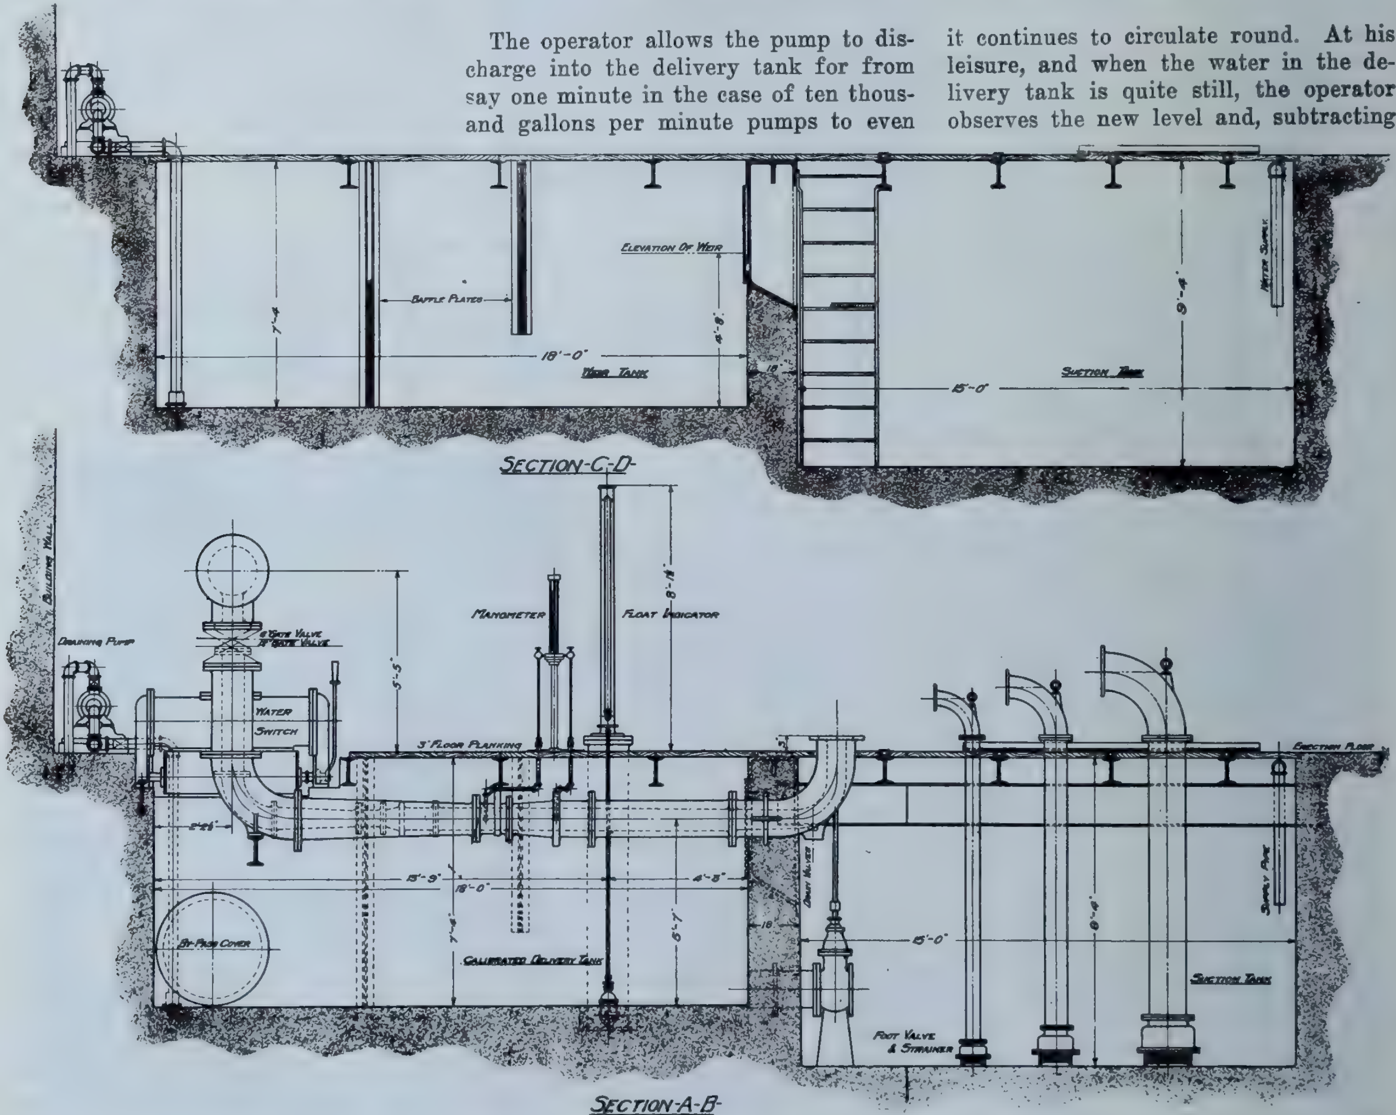

FIG. 5. SECTIONS OF WEIR, SUCTION AND DELIVERY TANK, SHOWING SUCTION PIPES AND METERS.

it from the original level, arrives at an exact volumetric measurement of the water passing through the pump. Note here also that the water is still passing through the Venturi meters, thus checking them against the delivery tank. Thus, the Venturi meter checks the weirs, and the volumetric measurement checks the Venturi meter.

For quantities over 10,000 g.p.m. the discharge is delivered direct into the delivery tank through by-pass into the weir flume and over the largest weir which, having been checked up to 10,000 g.p.m. may reasonably be assumed to be exact for larger quantities.

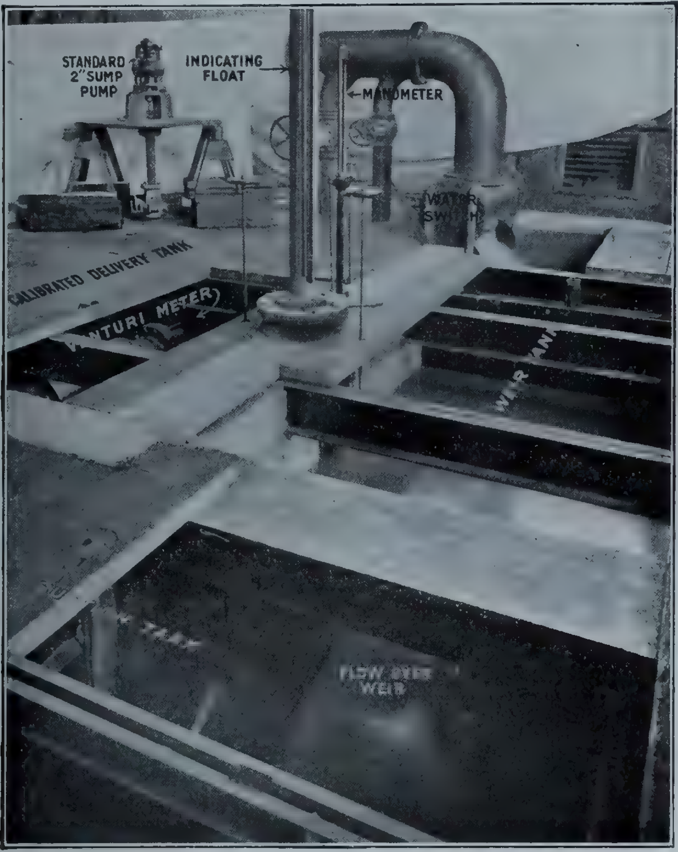

FIG. 7. FLOOR REMOVED, SHOWING WATER TANKS AND WEIR.

Fig. 7 shows part of the flooring removed with water flowing through the water switch into the weir flume and over the weir.

Fig. 2 shows a closer view of manometer and float, also illustrates the possibility of preparing and setting-up, for test, two pumps at the same time.

There is also a complete electrical testing department, fully equipped for making all tests necessary to determine the performance curves of motors, up to the largest sizes. A Prony brake equipment is also available for testing the smaller sizes. Power is received in the electrical testing department from 3-wire d.c. factory circuit at 220 volts; is then transformed by means of suitable motor generator sets and transformers, and then relayed to the testing table in the pump testing department shown in Fig. 1, where the readings of power input to the machine under test are made. Direct current at 110-220 and 550 volts, and alternating current at all standard voltages and frequencies are available. The power available is 400 h.p. for d.c., and 60-cycle a.c. motors, and 200 h.p. for 25-cycle a.c. motors.

It may also be mentioned that steam inlet and exhaust pipe connections are available at the test plant and small or large steam turbine-driven pumps can be as easily tested as motor or belt-driven units.

PREVENTING STEAM BOILER ACCIDENTS.

THE following instructions for boiler operation and repair, taken from the book of rules issued by the Inland Steel Company, should prove of interest to all boiler owners and operators.

1—Two men should always work together when cleaning out boilers, it being the duty of one man to remain on the outside all the time and in a position to see the man working inside so as to give assistance in case it is needed.

2—Never go into a boiler until you have locked the steam valve and closed all other valves.

3—Before entering a boiler, put a torch or candle inside to determine the presence of gas or bad air.

4—In cutting a boiler in and out, use the non-return valves exclusively, in order to insure their proper working. Should the non-return valve fail to work in any instance, notify the foreman immediately.

5—The automatic valves should be examined sufficiently often to insure their prompt action in emergencies, such as the bursting of tubes.

6—When boilers are taken off for cleaning, the main stop valve in the steam connections should be shut off and dependence not put on the automatic quick-closing valves alone.

7—A sign, "Danger, do not move," should be hung on the steam valve of any boiler when the latter is shut down.

8—Never open a slide or valve when a danger sign is attached and until you have seen that no one is in the boiler.

9—Safety valves should be tested every shift.

10—When opening up any steam line take the following precautions:—(a) Open all available drips; (b) warm the line by opening the by-pass when possible, or by opening the stop valve sufficiently to warm it slowly; (c) never allow an inexperienced man to turn steam into a cold line, unless accompanied by the foreman; (d) never open the main valve until certain that the line is thoroughly heated.

11—When starting up a boiler that has been dead, raise steam slowly, drop the pressure a few pounds on remaining boilers in the battery, and do not open the stop valve until the gauge on the dead boiler shows the same pressure as the other boilers; then open the stop valve slowly.

12—All steam trape taking care of large lines should be kept clean and in working order, as this is the only safe way to remove water from the line. Should a trap get out of order and it is impossible to repair it at once, the bypass should be opened sufficiently to eliminate all water that might collect. Blow off boilers every shift.

13—Leaks in pipes. flanges and gaskets should be repaired at the earliest possible moment, as they may be caused by defective material.

14—Keep the water glasses clean and the tops and bottoms open by frequent blowing out every shift.

15—In determining water level, try cocks should be frequently used, and dependence not wholly placed on gauge-glasses.

16—Never tighten any bolts or nipples or do any caulking while steam pressure is on the boiler.

17—Take great care in cooling and handling flue dust, as it is liable to fly, slide and explode, causing bad burns. Never step on it.

Breakdowns of Stationary Engines, Their Cause and Cure-III.

By Michael Longridge

The accompanying article, which formed the subject of a recent lecture before the Graduates' Association of the Institution of Mechanical Engineers, is one of special interest to power plant operatives. While this is so, the fact that faulty design and careless installation have played a large part in many "smash-ups," makes the advice relative thereto of considerable value to those also whose work lies in these particular spheres. The author of the paper is the well-known Chief Engineer of a large and leading English power plant equipment insurance company.

IN our March issue the contributory part that flywheels, valves, and valve gears, pumps, bed-plates and cylinders, played in the matter of stationary engine breakdowns was discussed. In the present article the relative place which pistons and piston rods, connecting rods and crank pins occupy is dealt with.

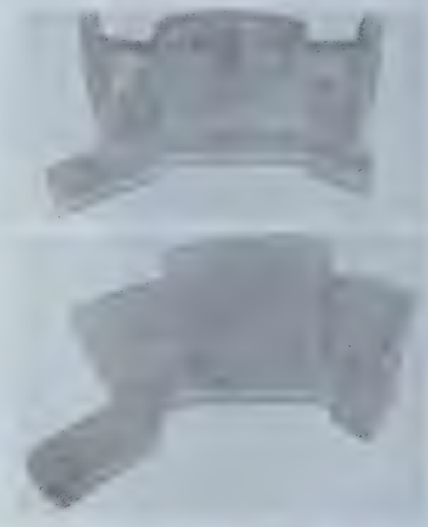
Pistons and Piston Rods.

Previous to 1899, breakdowns originating in pistons averaged 2.5 per cent. of the total breakdowns. Since then the average has been 4.8. The rise came suddenly soon after the rise of steam pressure to 160 lb., but I do not know that there is any connection between the two. During the last three years, 47 per cent. of these breakages have been caused by stray screws, or bolts, or broken rings; 17 per cent. by water, and the rest in various ways. When the substitution of plain pistons, with cast iron rings sprung into grooves, for pistons with junk-rings and fancy packings is complete, breakdowns from piston breakages will be halved.

Breakages of piston rods occur nearly always at the cotter-holes at the crosshead end, and are due to concentration of stress at the edges of the cotter-holes, as explained by Dr. Unwin on page 223 of the Part II. of his "Machine Design" 1912 edition. I indorse his explanation, and Figs. 17 and 18 afford convincing proof that cotters do bend in the way indicated by the drawing in his book. These figures are from photographs of two pairs of folding-wedges from the piston-rods of two old beam-engines after exhibitions of water in the cylinder. I would have shown single cotters, such as are generally used, but I, unfortunately, have none by me at the moment; moreover, I am not sure that folding-wedges are not preferable to single cotters, because a piece with parallel sides is easier to fit accurately than a tapering wedge; but if they be used, it is clear that the position of the pieces shown on the cut should be reversed, the broad piece should bear on the rod, and the narrow on the crosshead.

Connecting Rods.

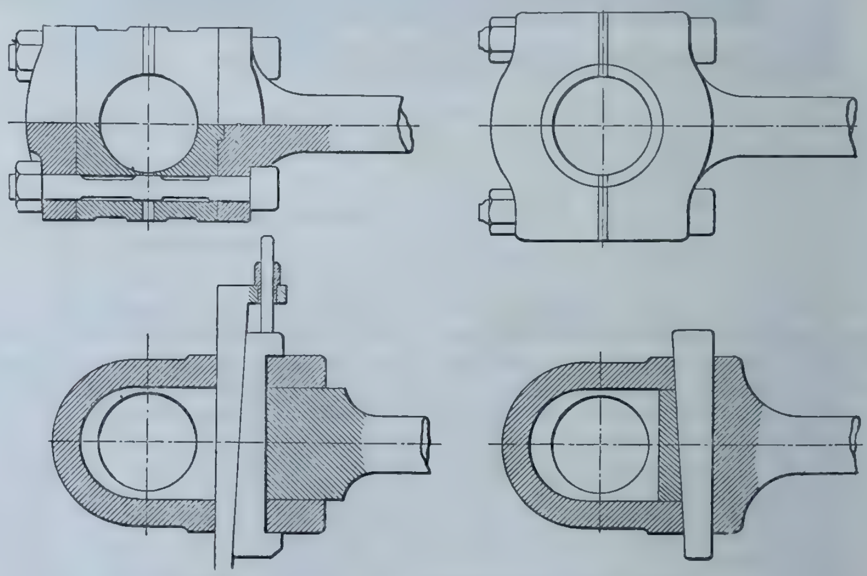
Fractures in connecting-rods occur generally at the ends which couple the rods to the crank-pins or crosshead centres; sometimes in the forks, when the crosshead ends are forked; and rarely in the body of the rods.



FIGS. 17 AND 18. PHOTOGRAPHS OF TWO PAIRS OF FOLDING WEDGES FROM PISTON RODS OF TWO OLD BEAM ENGINES, AFTER EXHIBITION OF WATER IN CYLINDERS.

The commonest types of end fractures are:—The box end or closed eye, Fig. 22; the open strap secured by gib and cotter, Fig. 21; and the marine end with cap and bolts, Figs. 19 and 20. Of the three, the marine end, Figs. 19 and 20, is, in my experience, the least safe, because of the frequent breakages of the cap-bolts, usually at the junction of the head and shank, or at the screw thread. The principal causes of these breakages are repetitions of stress or blows, abrupt changes of form, cross-bending stresses produced by the inertia of the rods.

The antidotes for the first are probably spare bolts, to give alternate periods of rest and service. Annealing is risky in unskilled hands. For the second, large fillets at junctions of heads and shanks, gradual reductions of diameters in shanks, and threads with rounder roots than the British standards. Fillets, cones, etc., at changes of section must be very neatly finished where they merge into the cylindrical parts, and threads very carefully chased, especially in steel, to leave nothing in the nature of cuts or scratches to initiate cracks. Stiffer palms and caps, also are often needed to prevent deformations, which would be apparent on reference to an india-rubber model; with consequent concentration of stress on one side of the bolt.



FIGS. 19, 20, 21, 22. CONNECTING ROD ENDS.

For the third, bolts with areas instead of diameters, approximating to half those of the rods, and the substitution of jaws, Fig. 20, long enough to hold at least one of the brasses, for palms, Fig. 19, are suggested. Rods like Fig. 19 should be tabooed, for it is easy to imagine the effect of a cross-bending stress if there be any wear or slackness. Bolts of small engines are more heavily strained by this stress than large, because the ratio of their length to their diameter cubed is greater. For connecting-rod bolts, wrought iron is a safer material than steel.

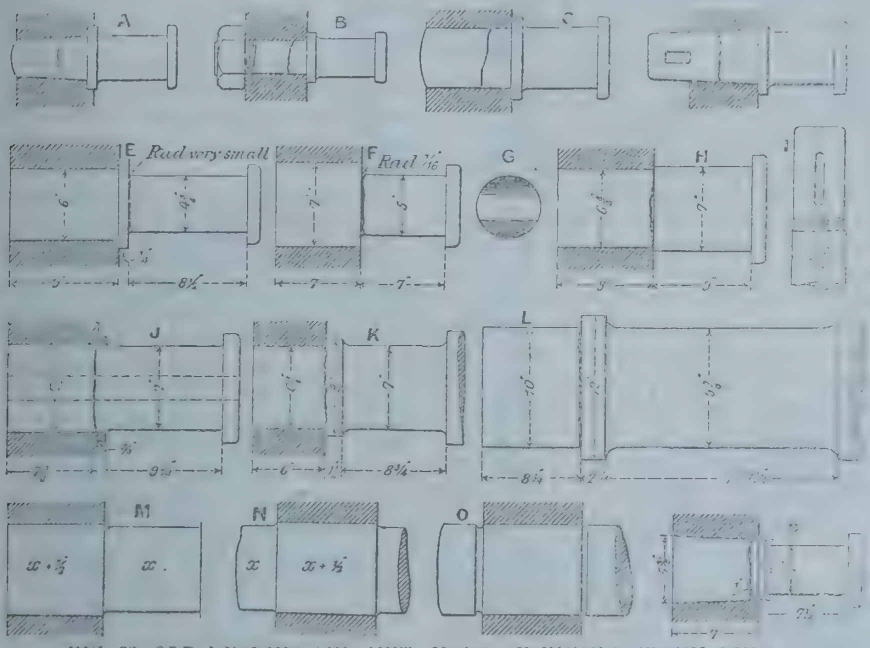


FIG. 23. OLD DESIGNS AND METHODS OF FIXING CRANK PINS.

Open straps, Fig. 21, secured by gibs and cotters are but little safer than marine ends. The jaws of the cotters wear, the straps open under the cross-bending stress produced by the inertia of the rod, and break, generally through the oil-hole. Fracture almost invariably begins on the inside surface, and when it has extended a certain distance, often not far enough to be visible above the flange of the brass, the strap breaks and opens out. Never trust a strap till you have seen the inside surface. Open straps should be kept closed on the butts of the rods by bolts in place of, or in addition to, the gibs.

Of the three forms, the box end, Fig. 22, is undoubtedly the most reliable. Fractures, when they occur, usually commence, as in the straps, on the inside surface at the hole for the lubricator, but extend slowly enough to be discovered before the rod gets free. Among more than 6,000 breakdowns of engines of various kinds I can only find one where fracture of a wrought-iron or steel box-end caused damage to an engine, and this was the fault of the engineer-operator, for the fracture had been visible on the outside surface of the end as far as the lubricator-hole some time before the rod gave way.

Crank-Pins.

The history of crank-pins has been very like that of cylinders, showing a rising percentage of breakages, culminating in the five years 1894-1898, and then falling. The rise was due to bad designing, improper methods of fixing, and over-loading; the fall to the more general adoption of the right method of fixing, combined with reduction of stress. In my early days, stresses of 12,000 to 14,000 lbs., per sq. inch were common, and stresses of 50 per cent. higher were frequently met with. Samples of the old designs and methods of fixing are shown in Fig. 23. In Fig. 23, (A), (B), (C), (D), are examples of pins with conical or cylindrical shanks fitted into the cranks and secured by riveting, screws and nuts, or cotters. They usually broke inside the crank-eyes, because the fit was not accurate enough to prevent slight movements which wore and enlarged the ends of the crank-eyes next the journals, thus throwing back the point of support and increasing the bending moments.

It will be noticed that the pins were put usually in from the faces of the cranks, so that they could come out and wreck the engine when they broke. Typical examples are indicated at (E) and (F). They have not sharp corners at the junctions of the journals with the collar, though such were not unusual; but the fillets provided, 1-16 in. to ⅛ in. radius, are too small to be effective. Both pins were of steel. The fractures were due to bending stresses. They commenced at the parts of the circumference nearest to, and furthest from the crank-shaft, and extended inwards as shown on the shaded part of (G), Fig. 23. The lives of these pins were 14½ and 104 million revolutions, and the bending stresses 17,500 and 11,500 lbs. per sq. in. respectively.

The breakage of (H) may have been entirely due to the abrupt change of diameter from 6¾ in. to 7 in. for piston-rods in direct tensile stress will break with a smaller change than is shown at (I), Fig. 23; but probably it was started by the shearing action of the edges of the crank-eye, when cooling and contracting upon the pin.

The failure of the pin (J) can be attributed to nothing else but shear. It was made of steel, of 60,000 lbs. tensile strength, 29½ per cent. extension in 6 inches, 60 per cent. contraction of area, and a strip cut out of it after the breakdown, was bent cold nearly double without cracking. It broke under a stress of 9,400 lbs. per sq. in., after 5¾ million revolutions. I think the crank-shafts (K) and (L), Fig. 23, are similar cases. The stresses and lives were: For (K), 8,200 lbs. per sq. in., and 17 million revolutions; and for (L), 5,000 lbs. per sq. in., and 218 million revolutions; the longer life of (L) being due to the lower stress, and probably to a lower pressure exerted by the crank in cooling.

I do not think the effect of the pressure of sharp edges or even of scratches in starting skin-cracks in steel, or the almost inevitable extension of such cracks under recurrent stresses, is sufficiently appreciated. About scratches I shall say a few words presently. Of shrinkage, I say without hesitation that the portion of the internal piece upon which an external piece is to contract should be of larger diameter than the adjacent portions, and that the external piece should entirely cover the enlarged portion of the internal.

At (M), Fig. 23 is shown how a crank-pin should be put in, while (N) and (O) show the proper method of shrinking a piece upon a shaft. It is to the adoption of this principle by many engine-makers, combined with reduction of working stress to 8,000 lbs., or 9,000 lbs. per square in., that the reduction in the number of crank-pin breakages must be attributed. The failure depicted in (P) is one of those things "no feller can understand."

Engineers' District Council.—A district council of engineers and firemen was formed on April 25, and will be known as "the District Council of Steam and Operative Engineers of Montreal and the Vicinity." The trades represented in the organization will be the portable engineers, Local 550; Court Partier, of the stationary engineers, and the International Brotherhood of Firemen, Local 233 Officers were elected as follows: President, H. Girardot; vice-president, A. Archambault.

The Design and Construction of Hydraulic Turbines*

By H. B. Taylor, M. Am. Soc. M,.E.**

The development of the water powers of the world has turned the inventive genius of men in the direction of machine design distinct from that akin to steam operation, and the achievement realized in the latter sphere is being to a large extent duplicated in the production of engines whose motive power is derived from the harnessing of waterfalls in this and many other countries where the particular natural resources are available.

METAL FEATURE OF CORROSION.

While corrosion is primarily caused by faulty design, some metals are more prone to its action than others. For example, bronze resists corrosion better than does either cast steel or cast iron; but if the runner is so designed as to permit corrosion to take place, it matters little what metal is used. Runners regulated by means of cylinder gates are particularly subject to corrosion, owing to the eddies produced behind the cylinder gates at fractional gate openings. Corrosion will often develop in a runner if the turbine be operated continuously at low gate openings. The falling-off of the efficiency of a turbine at low gates is an indication that the hydraulic conditions within the runner are greatly disturbed, and this disturbance tends to promote corrosion. High specific speed runners, if applied to high heads, are also subject to corrosion, owing to the high velocities to be dealt with and the difficulty in making the water follow the radical curves characteristic of the vanes of these runners.

Cast iron to-day is used as a material for runners to a much greater extent than heretofore, and, as a result of careful designing, it has been successfully employed under conditions which, until recently, were thought to be impossible. As an example, in the case of the four 18,000 horse-power turbines operating under a head of 420 feet in the plant of the Great Western Power Company, it might be mentioned that two of the units were equipped with runners of special bronze, the third with a runner of cast steel, and the fourth with a runner of cast iron. These turbines have been in operation since 1908 and a recent inspection has shown all of the runners to be in equally good condition, there being no evidence of serious corrosion.

Cast steel is thought to be the most undesirable metal from considerations of corrosion, on account of the unavoidable roughness of the surface. In the casting of steel runners it is very difficult to make the metal flow into the thin vane sections without chilling, unless extremely high temperatures are employed. These temperatures often result in the production of uneven surfaces, on account of the difficulty of obtaining sufficiently refractory material for the surfaces of the mold.

Draft Tube Relation to Corrosion.

Corrosion has often been greatly accelerated because of poor draft tube conditions. It has been only recently appreciated that the total draft head acting on the turbine, or the negative pressure on the discharge side of the runner in feet of water, is equivalent to the vertical distance from the tailwater elevation to the runner, plus the head corresponding to the velocity of the water as it passes through the discharge section of the runner, minus the losses in the draft tube, minus the head corresponding to the velocity at the discharge section of the draft tube. In modern plants, the last two factors entering into the total draft head have been kept within negligible values.

It is evident that should the total draft head, or the sum of the static draft head and the velocity head at the runner discharge, exceed the height of the water barometer, the continuity of flow of the water on leaving the runner is destroyed. When the absolute static pressure in the draft tube falls to a value equal to the vapor tension corresponding to the temperature of the water the water will vaporize and the draft tube will not be filled with a solid column of water from the tailrace to the runner. Therefore, the placing of a turbine simply within 34 feet from the elevation of tail-water is no indication that the elevation has been properly chosen; for aside from the limitations outlined above, it is also necessary to allow at least three or four feet margin between the total draft head and a perfect vacuum to prevent the breaking of the column of water in the draft tube due to inertia effects resulting from sudden changes of load on the turbine.

It must also be borne in mind, and this is a point which has been frequently overlooked, that in figuring the margin between the maximum vacuum and the total draft head, the maximum vacuum should be considered for the particular elevation above sea level at which the turbine is to be installed. The fact that the question of draft head has not been clearly understood has resulted in the location of a great number of turbines at such heights above tailwater that the benefit which would otherwise be secured by means of the draft tube has been largely sacrificed. In a number of cases where the draft head has been excessive corrosion of the runner vanes has developed at a rapid rate, and this corrosion has also attacked the runner band and draft tube in the neighborhood of the runner.

If, therefore, the runner vanes be so designed as to give sufficient contraction to the stream to prevent the water leaving the vane surfaces, if the speed selected be consistent with good hydraulic conditions, and if the elevation of the turbine above tailwater level be properly selected, there is no reason for anxiety over the possibility of corrosion developing to any appreciable extent. In respect to erosion, however, although the best means are used in resisting its action and high factors of safety are adopted in all parts of the machinery which may be subjected to it, erosion must necessarily be expected wherever the quality of the water is such as to produce it.

High Capacity Runner, and Vertical, Single Runner Turbine.

Until two years ago, a very large majority of turbines applied to low heads were either of the vertical shaft, multi-runner type, or of the horizontal shaft, multi-runner type. The reason for using more than one runner on the shaft which, from a mechanical standpoint, is not desirable, was that this arrangement permitted high rotational speeds, and, therefore, economic sizes of generators. During the past two years, however, the general adoption of the single runner, vertical shaft turbine for low and medium heads, has been witnessed. This change in the type of unit has been made possible by recent progress in the design and development of high capacity runners. Thus, for a given head and speed it is now possible to secure from a runner a greater output than was possible two or three years ago; or, conversely, for a given head and capacity it is possible to operate the more recently designed runners at a much higher rotational speed than was the case with runners designed a few years ago. This increase in the capacity of runners has been secured without a sacrifice of maximum efficiency and with only a small sacrifice in the efficiency at fractional loads.

CROSS SECTION OF POWER HOUSE, APPALACHIAN POWER CO., DEVELOPMENT NO. 4.

Viele Blackwell & Buck, Consulting Engineers, New York.

In referring to the capacity of a runner, there is a certain relation between head, speed and power output which is best expressed by a theoretical characteristic known as "specific speed" (Ns). This characteristic was first introduced by German engineers. It gives us a means of comparing the relation between the conditions of speed, head and power of a runner in one installation with the same conditions relative to a runner in a totally different installation. This comparison is made after the conditions governing the design of both runners have been reduced to a common base, viz., specific speed.

The specific speed of a runner may be defined as the speed at which any runner will operate when it is reduced to such a size that it will develop one horsepower when operating under a head of unity. The numerical value, expressed in the metric system, of the specific speed of any runner may be found by first calculating the speed and power output of the runner under consideration for one metre head, and then mathematically reducing the runner in size until it will deliver one horse-power. The speed of this reduced runner, when operating at its point of maximum efficiency is its rated specific speed, and this speed is expressed in the formula

$$Ns = RPM \times \frac{\sqrt{HP}}{h5/4}$$

the quantities being expressed in the metric system. For converting this to the foot-pounds system of units, the formula is

$$Ns = 4.45 \times RPM \frac{\sqrt{HP}}{h5/4}$$

in which the horse power and head are expressed in the foot-pounds system, while the Ns remains in the metric system. The specific speed as calculated from this latter formula is the one generally used. In figuring the specific speed of any turbine having more than one runner, the horse-power used in the formula, of course, is the output of each runner.

An examination of the formula will show that for a given r.p.m. and head, the h.p. output is proportional to the square of the specific speed; also that for a given head and h.p., the r.p.m. of a turbine is proportional to the specific speed.

Five years ago, a specific speed of 275 was considered to be quite high, while to-day a specific speed of 400 is secured together with as high a maximum efficiency as was previously secured with a specific speed of 275. Thus, it is now possible with very high efficiency to secure for a given condition of head and power, and with the same maximum efficiency, a speed in the neighborhood of 50% greater than was possible five years ago; or, for a given head and speed, an increase of approximately 100% in the horse-power can be obtained.

With the highest specific speed which could be secured five years ago, the resulting r.p.m. for a vertical shaft, single runner tubine for low heads was, in a great majority of cases, such as to make the cost of both the turbine and generator prohibitive. During the last two years, however, with runners of increased specific speed, a much higher rotational speed can be secured for the same head and power, so that the turbine and generator designs have become thoroughly practical and economical. Although it is true that the rotational speed secured in such a turbine is low when compared with the speed secured with turbines of the same specific speed and having two or more runners, there are many mechanical advantages involved in the use of the single runner vertical turbine for low heads which more than over-balance the increased cost of the generator. The following are among the recent prominent low head plants for which the single runner vertical shaft turbines have been adopted:

Appalachian Power Co., New River, Virginia:

Development No. 2, four 6,000 h.p. units, head 49 feet; speed 116 r.p.m.

Development No. 4, three 3,500 h.p. units, head 34 feet; speed 97 r.p.m.

These turbines hold the highest record of efficiency ever obtained, namely 93.7%.

Mississippi River Power Co., Keokuk, Iowa:

Present installation, fifteen 10,000 h.p. units, head 32 fet, speed 57.7 r.p.m.

Ultimate installation thirty units.

Georgia-Carolina Power Co., Stevens Creek, Georgia:

Present installation, five 3,125 h.p. units, head 27 feet, speed 75 r.p.m. Ultimate installation, ten units.

Alabama Power Co., Lock No. 12, Coosa River, Alabama:

Present installation, four 17,500 h.p. units, head 68 feet, speed 100 r.p.m.

Ultimate installation, six units.

Cedars Rapids Mfg. & Power Co., St. Lawrence River, P.Q.

Present installation, twelve 10,800 h.p. units, head 30 feet, 55.6 r.p.m.

Ultimate installation, eighteen units.

These will be the largest turbines in the world in point of dimensions, and will each weigh approximately 1,250,000 pounds.

Laurentide Company, Grand Mere, P.Q.:

Present installation, six 20,000 h.p. units, head 76 feet, speed 120 r.p.m.

Ultimate installation, ten units.

These will be the highest powered single runner vertical turbines in the world to date.

Northern Ontario Light & Power Co., Cobalt, Ont.

Present installation, two 1,500 h.p. units, head 30 feet, speed 150 r.p.m.

Turners Falls Co., Turners Falls, Mass.

Present installation, three 9,700 h.p. units, head 54 fet, speed 97.3 r.p.m.

Had these plants been built five years ago, it would have been impossible to install vertical shaft single runner units of the same capacity, owing to the low speed and the resultant size of turbines and generators. For the same capacity, it would have been necessary to install turbines with more than one runner, or if single runner vertical shaft turbines were used, the capacity of each would necessarily have been considerably less than that of the turbines adopted, owing to the excessive dimensions with which it would have been necessary to deal.

SUN POWER PLANT AT CAIRO, EGYPT.

MR. FRANK SHUMAN, who is chiefly responsible for the design of the sun system of power production, gave in a recent paper before the Manchester Association of Engineers particulars of the plant erected at Cairo, because that is the nearest place to the tropics easily accessible, though it is not the ideal position for a sun-power plant, being 30° N. The equator would be the ideal position, but up to 20° N. and 20° S., sun-power is considered quite satisfactory. In fact, it has been shown that even at Cairo profitable work can be done by sun-power plants.

General Arrangement.

There steam is generated in improved forms of sun-heat absorbers, of which there are five, each 13 ft. 4 in. wide at the top and 204 ft. long. They are approximate parabolic troughs for catching the sun's rays and concentrating them upon the boiler swung at the focal point. These heat absorbers are placed about 25 ft. apart in the clear, so that they will not shade each other when the sun is low in the morning and late afternoon. Their axis point north and south and they turn from east to west on their axis to face the sun. The mirrors are set in a light steel frame, each one at the proper angle to throw the sun's rays upon the boiler, and consist of ordinary sheets of third quality window glass 1/16 in. thick, silvered on one side, the silvering being protected from the atmosphere. At the focal point of all the light rays there hangs a cast iron boiler, which is tubular at the top and flat at the bottom where is located the water space.

This boiler is 15 in. high, and is hung on light rods in such manner that expansion and contraction will not affect it. The heat absorbers are a distinct advance upon those in use at Philadelphia. They are set on crescent-shaped frames, which roll on a system of small rollers, while racks and pinions are provided for turning the absorbers from a low eastern aspect in the morning to a low western aspect in the evening, the necessary power being provided by the steam engine and friction clutch, an adaptation of the thermostat being used to throw the clutch in and out of gear. The thermostat is placed immediately below the boiler and remains in the shade as long as the absorber points correctly to the sun. When the sun moves ahead a little and the sunlight strikes the thermostat, the clutch is engaged, and the absorber is turned westward accordingly. When the thermostat is shaded again, the clutch is released and the absorbers stand still, and so on.

The Engine Feature.

The engine is of special design to utilize low-pressure steam to the best advantage, and, according to the author, is extremely efficient, giving one brake horse-power per 22 lb. of steam at atmospheric pressure. It has cylinders 36 in. by 36 in., gives its power at 110 revolutions per minute. The pump is of the reciprocating type, and a small petrol engine is provided for creating a vacuum in the condenser for starting. The plant commences to make steam at about 7.30 a.m., in midsummer, and the maximum is reached between ten and two o'clock. The amount gradually decreases until 5.30 p.m. Tests made show that the average production is 1,100 lb. of steam at 15 lb. absolute pressure per hour for a ten-hours' day.

Test Data.

According to comparisons made, the sun-power steam generator will compete in the tropics with a coal-burning steam generating plant which can obtain its coal at only $2.50 per ton delivered to the furnace doors. Any excess in the cost of coal burned beyond this figure is clear profit in favor of the sun-power plant.

Safety Provisions Relative to Transmission Machinery—I.

By W. Sydney Smith.

An official report by the Inspector for Dangerous Trades in England, regarding fencing and safety precautions for transmission machinery, has been issued. It explains the structural and administrative safeguards with regard to the several parts of transmission machinery which experience shows to be needed for the protection of persons employed.

IT is a dangerous fallacy to assume, as is often done, that slow-running shafts, or shafts of large diameter, are free from danger and need not be safeguarded. Every shaft is required by the Factory Acts to be securely fenced, irrespective of its speed or size, unless it be equally safe by position or construction as if it were fenced. Unfenced smooth shafting of 12 ins. in diameter and shafts running at less than 26 revolutions per minute have been responsible for fatalities. The following rules should apply to horizontal, vertical and oblique shafts:—

(1)—Shafts less than 6½ ft. above the floor level should be securely fenced.

(2)—Shafts more than 6½ ft. above the floor level should have those parts securely fenced which are less than 6½ ft. from any point (work bench, platform, shelf, cupboard, machinery, boiler, plant, pile of goods, ladder or other structure, to which workers may need occassional acess for such purposes as lubrication, cleaning, manipulating belts, or other work of maintenance of transmission machinery; lime-washing, painting, electric wiring, cleaning, opening or shutting windows, or any occasional work other than the work of maintenance of transmission machinery, except where the shaft is stopped at the time any worker approaches within 6½ ft. of it, or the shaft is moving at less than six revolutions per minute at the time any worker approaches the transmission machinery for the purpose of adjusting belts, and due provision is made (by signals or otherwise) for prompt stoppage at the first sign of danger.

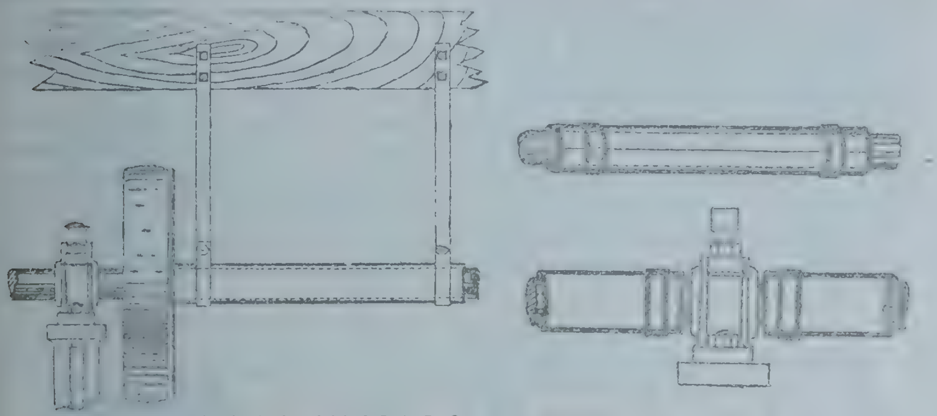

FIG. 1. SHEET METAL OR MILLBOARD TUBES.

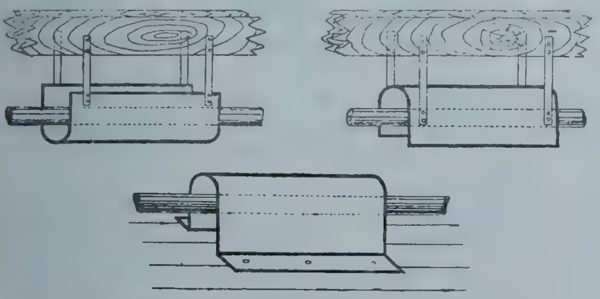

FIG. 2. SHEET METAL TROUGHS FOR PROTECTING REVOLVING SHAFTS.

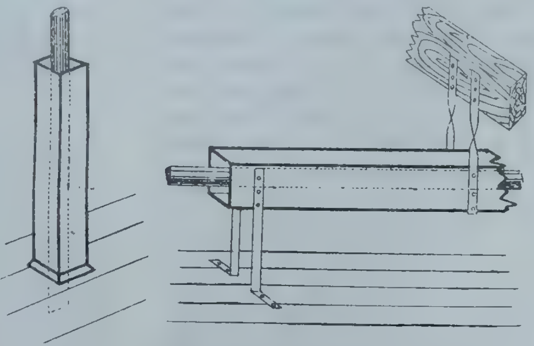

FIG. 3. WOOD CASINGS FOR PROTECTING REVOLVING SHAFTS.

These rules are embodied in the proposed regulations requiring shafting and other parts of the transmission machinery "within reach" to be securely fenced, if in motion, and the phrase "within reach" is defined as meaning "within a distance of 6 ft. 6 ins. in any direction from any spot on which any person employed or working may have to stand or pass at any time, either in the course of his employment or incidentally thereto."

Measurement in an upward direction only will not suffice. Dangerous transmission machinery may be "within reach" in a horizontal or even downward direction from the working place of a person employed—for example, it may be near or below the level of the floor on which he has to stand; or he may have to work at the edge of a pit or on a ladder, with risk of falling into unfenced transmission machinery below.

Although the definition makes no exception for an intervening fence of any kind, even a floor or wall, no difficulty can arise in practice since the requirement of secure fencing may be already met.

Type of Fencing.

The type of fencing needed varies with the position and arrangement of the transmission machinery, but shafts are usually fenced, either by complete or partial casings, consisting of fixed or loose sleeves, or by guard rails so placed as to prevent access. Tubes of sheet metal or mill board, Fig. 1, sheet metal troughs, Fig. 2, and wood casings, Fig. 3, make excellent guards. These may be attached by suitable brackets to such supports as pedestal bearings, hangers, wall-boxes, overhead beams, walls or flooring.

Wire netting is sometimes similarly used, but is less cleanly than complete casings of sheet metal or wood. Millboard tubing, somewhat larger in diameter than the shafting, may be slipped over the shaft as a loose sleeve, which will revolve when the shaft is in motion, but will stop immediately if a person comes in contact with it. Millboard tubes are made of varying lengths, in halves or split on one side. The parts can be readily fastend together by means of thin wire or metal clips which should be free from projections. Loose metal sleeves are often similarly used for fencing shafting and projecting shaft ends.

When shafting is fenced with partial casings, care should be taken that the revolving shaft is covered sufficiently by the casing. Many accidents have occurred on shafts protected on two or three sides, only, leaving the shaft exposed in one or more positions. Shallow partial fencing, such as a trough or single board placed under, over, or adjacent to shafting, is dangerous. For this reason, complete casings are preferable to partial guards unless deep troughs of wood or metal are used.

In some instances, owing to the number of pulleys upon low lines of shafting, as in flour mills, saw mills, engineering factories, and similar works, the shafts cannot be encased. Guard rails are then necessary. The rails should not be too wide apart and the space between shaft and rails, whenever the diameters of the pulleys or the positions of the driving belts permit, should be about 12 inches. If it exceeds this, a person may enter within the space, and if less than this, accidents may happen through contact with the shaft by clothing or materials, or by persons falling against the rails.

In clothing factories, where sewing machines are generally driven by low shafting under the machine benches, the shafts and pulleys are often fenced by rods of iron or by fixed boards, and occasionally by hinged boards. The latter are dngerous, as there is always the chance of the workers throwing back the guard and coming in contact with the shaft. Where rails are used these should be sufficiently strong to resist bending if used as foot rests.

Care is necessary as to position of the guards and spacing of rails and boards to allow, with safety, the adjustment of driving bands and the necessary cleaning under benches, but at the same time to avoid the possibility of the hair being caught. Such accidents generally occur when a worker with loose hair is sweeping under a bench or picking up some object which has fallen on the floor in the vicinity of the shafting. It is usually found either that the guards were fixed originally too far apart, or that a rail had been bent downwards, leaving sufficient space for the head to approach the shaft and the hair to become entangled. A space of 8 inches between the floor and lowest guard, with spaces not exceeding 6 inches between the higher rails or boards, will not interfere with cleaning or manipulation of belts, and will almost entirely remove the risk of accident.

In the latest type of sewing machine benches, the machines are driven from a shaft, fixed a few inches below the bench, and completely encased in planished steel tubing; while the shaft is directly driven by an electric motor co-axial with the shaft. The fronts of the pulleys and bands driving the machines are fenced by cast metal grids. In general, where females are employed, greater care is needed as to the fencing of transmission machinery in order to avoid accidental contact of the worker's hair or clothing with revolving parts; complete encasing of shafting, with protection of pulleys by side plates, as shown in Fig. 1, is preferable.

Whenever it is necessary to cross low lines of shafting fenced by rails, there should be gangways or steps at suitable intervals so as to fence the shaft, with hand rails on either side of these crossing places (Fig 4). Where the shafting is high enough to allow passage underneath, but less than 6½ ft. from the floor level, the shaft should be completely encased at the passage way (Fig. 5).

High shafting in motion must be approached from time to time by engineers, greasers, beltmen and other persons employed in oiling, cleaning, adjusting belts and similar work of maintenance. Where space permits, there should be an overhead gangway or service platform, sufficiently near the shafting to admit of the necessary work being done in safety, and yet at such a distance as to prevent contact with transmission machinery in motion. The platform should have guard rails to a height of 3 ft. and a skirting board to prevent the worker falling under the rails or fall of tools on persons below. Failing overhead gangways, the approach may be made by a safe type of ladder, but in such cases there is always risk of accident unless the shafting in the vicinity be fenced.

High shafts are often permanently encased for about 2 ft. on either side of each bearing, the casings being fixed by suitable brackets to the bearings or hangers. Ladders are sometimes provided with an inverted trough, which rests on the shaft, and so fences the portion temporarily. These may be used where there is ample space between pulleys, couplings and bearings. If there be lubricators, or self-lubricating bearings, oiling can generally be done at rest, but replacing of belts on pulleys is impossible in many cases unless the shafting and pulleys are moving. With various types of belt mounters this operation can be done in safety from the floor level at the ordinary working speed of the shafting.

Where pulleys are close together, fencing of the shaft is often impracticable, and if the worker approaches unfenced transmission machinery in motion to adjust belts, in addition to contact with the revolving shaft, there is always the danger of contact between belt and pulley, or belt and shaft. Hence, in cases where approach to unfenced shafting is necessary, it is imperative that the speed of the shafting be previously reduced to a safe limit.

Severe accidents have occurred on shafting moving at only 9 revolutions per minute, and a fatal accident on a shaft moving at only 5½ revolutions per minute; but a speed not exceeding 6 revolutions per minute may be considered safe for the dangerous operations of manipulating belts by hand on transmission machinery in motion, provided due provision is made by signals or otherwise for prompt stoppage at the first sign of danger.

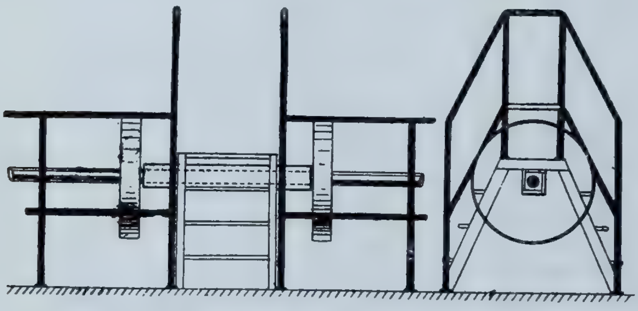

FIG. 4. FENCING FOR LOW SHAFTING WITH STEPS OVER SHAFTS AND HANDRAILS.

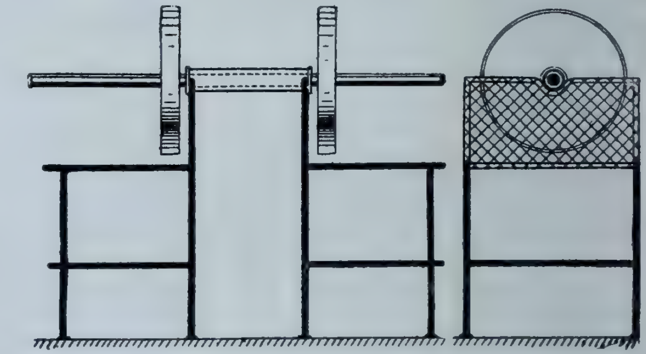

FIG. 5. FENCING FOR SHAFTING WITH FENCED PASSAGE-WAY UNDER SHAFT.

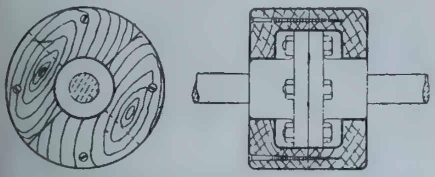
Couplings.

Concerning couplings, the report says that such projections as bolt heads, nuts, screws and keys should be prohibited in all new installations of transmission machinery. Shaft couplings should be constructed with countersunk bolts and nuts, shrouded flanges, or other equally safe devices. In existing installations, as shaft couplings are generally situated near bearings, all pro-



Wood discs in halves screwed together.

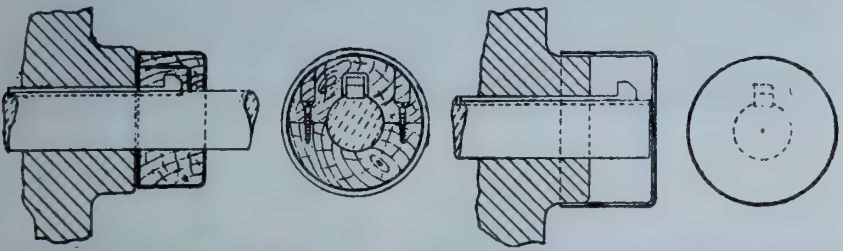
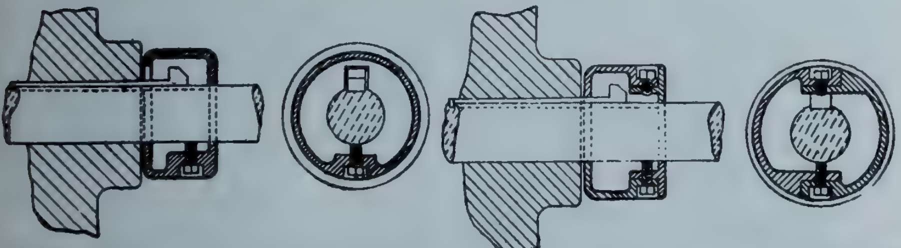
jections should be covered by smooth wood or metal casings if the shafting is ever approached whilst in motion. Various methods of fencing projecting coupling bolts as shown in Fig. 6.



WOOD CAP IN HALVES SCREWED TOGETHER.

SHEET METAL CAP ON PULLEY BOSS.



CAST IRON CAP WITH COUNTER-SUNK SCREW.

CAST IRON CAP IN HALVES SECURED WITH COUNTERSUNK SCREWS.

FIG. 7. GUARDS FOR PROJECTING KEY HEADS OF SHAFT COUPLINGS.

Collars.

Projecting set-screws on shaft collars should be prohibited on all new installations. Countersunk set-screws or other equally safe method of attachment should be provided. On existing installations of transmission machinery, as collars are always situated in close proximity to bearings and loose pulleys, projecting set-screws should be removed, replaced by countersunk set-screws, or covered with a smooth cap or guard if the shafting is ever approached whilst in motion. Figs. 8 and 9 show types of guards.

Wheels, Drums, Pulleys.

All appliances of this nature if less

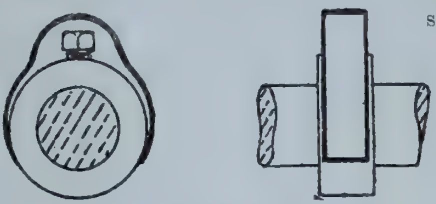


FIG. 8. STEEL CLIP GUARD FOR PROJECTING SET SCREW OF SHAFT COLLAR.

than 6½ ft. from the floor level or any place to which the workers have occasional access, should be fenced so securely as to prevent accidental contact by persons with parts in motion, but appointed persons, such as enginemen, oilers, and beltmen, may be allowed to approach unfenced drums and pulleys for the necessary work of manipulating driving belts and ropes at times when the speed of the shafting and pulleys does not exceed 6 revolutions per minute if adequate provision is made for prompt stoppage of such parts at the first sign of danger. Gear wheels, if situated as above, should be encased with metal guards fully protecting the teeth and rims with a portion of the guard hinged or sliding to facilitate lubrication of the teeth.

Partial guards for gear wheels are always inadequate, and may even be dangerous; though the ingathering teeth may be protected, additional points of danger are introduced between the teeth and the ends of the guard, and fingers, clothing, or cleaning rags may easily be caught unless the teeth are wholly covered. Complete guards, enclosing the whole of the wheels, have the advantage of preventing access of dust and also limit the splashing of grease. For these reasons gear wheels on overhead line shafting are generally completely fenced.

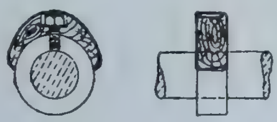

FIG. 9. WOOD GUARD FOR PROJECTING SET SCREW OF SHAFT COLLAR.

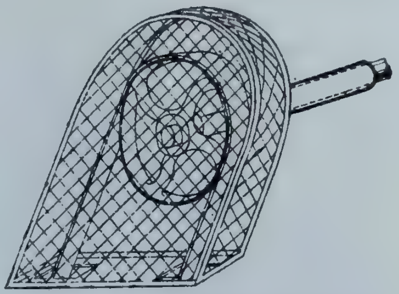

FIG. 10. WIRE NETTING GUARD FOR BELT AND PULLEY.

Sprocket wheels for chain drives should be fenced like gear wheels, if similarly accessible. Friction gearing is equally dangerous as toothed gearing at the intaking parts, but guard rails are generally sufficient for this type of transmission machinery if the fence be maintained in such position that the space between rails and dangerous parts cannot be entered by the workers.

The type of fencing for drums and pulleys is often determined by their position and the direction of the driving bands and ropes; the guards may generally be so arranged as to include fencing for both pulleys and bands, Fig. 10. Fast pulleys near the floor level are dangerous owing to the risk of clothing and feet becoming entangled between belt and pulley. These should be protected by guards, which should also fence the loose pulleys and driving belts. Fenders of wood or metal form satisfactory fences for pulleys in such positions. Guard rails are often so used; sheet metal, wire netting or perforated metal being added according to special circumstances where the pulleys are more exposed or greater danger exists owing to the employment of females.

Engineers Organize. — A meeting of licensed engineers was held on April 18, in the Sons of England hall, Medicine Hat, Alta., for the purpose of forming a local branch of the International Union of Steam and Operating Engineers. There was a good turnout and it was unanimously decided to go ahead with the formation of the branch.

Electrical Driving of Winding Engines and Rolling Mills-II*

By C. Antony Ablett, A.M. Inst. C.E. and H. M. Lyons, A.M.I.E.E.

Each inroad made by electricity into fields long held by the steam engine usually marks a distinct advance in engineering science. The authors show that the electrification of mine hoists and rolling mill machinery is not only fully as feasible as that of railways and other well-known applications, but that it has much greater flexibility in admitting of automatic control, safety devices, etc.

APPLICATION TO ROLLING MILLS.

NEARLY 60 large reversing mills are being driven electrically in different parts of the world, and a modification of the Ward-Leonard system has been installed in almost every case to meet these special requirements.

FIG 7. GENERAL VIEW OF THE ELECTRICAL PLANT FOR DRIVING A [illegible]-INCH REVERSING BLOOMING, ROUGHING AND FINISHING MILL AT THE SKINNINGROVE IRON WORKS. THE 12,000 HORSE-POWER REVERSING MOTOR WILL BE SEEN IN THE BACKGROUND. THE ILGNER MOTOR GENERATOR SET IS IN THE FOREGROUND, CONSISTING OF A THREE-PHASE MOTOR, TWO VARIABLE VOLTAGE DYNAMOS AND A 46-TON FLYWHEEL.

The power requirements of a reversing rolling mill impose much more severe conditions on the electrical plant than those of a large electrically driven hoist. With a large 36-in. or 45-in. blooming mill, ten to twelve passes are often made in a minute, and the power during individual passes may rise to 12,000 h. p. or more, while the total time of the passes, i.e., the total time that the ingot is between the rolls is very short compared with the total time taken to roll an ingot down to a bloom or billet. It is thus easily seen that the average power required from the power station is very much less than the maximum power which the mill motor has to give. For example, in many electrically driven blooming mills, the average power is only one-sixth or one-seventh of the maximum power. The diagrams in Fig. 12, in which the triangular or rectangular spaces show the work done per pass, illustrate how small the average power is, compared with the maximum power which has to be given by the mill motor.

In the case of an electrically driven hoist, the duration of a wind would be perhaps one minute, followed by a pause of 20 seconds or so, and the maximum power required seldom exceeds 3,000 to 4,000 horse-power, so that the average power is of the order of one-third of the maximum power. While, as has already been pointed out, it is frequently necessary to couple flywheels with winding engines it is always necessary to couple a flywheel to the motor generator set which supplies a reversing rolling mill motor, and to make provision so that the motor generator set falls in speed when the mill motor requires a heavy power to enable the flywheel to give up some of its power and then rises in speed again when the mill motor is not requiring power, thereby using the supply of the power house to store up energy in the flywheel. Experience has shown that in a steel works where electrical power is being generated in a blast furnace gas engine power station, the flywheel of the motor generator set has a very beneficial effect in keeping down the cost of this power station.

The flywheel of the motor generator set can be arranged so that it not only reduces fluctuations in the demand of power made by the mill motor to a minimum, but is also capable of reducing or even obviating peaks of short duration in the power demand, which may occur in other parts of the plant which are supplied from this power house. This is particularly the case where direct current power is being supplied. As the blast furnace gas engine has a very small overload capacity, this will obviate the necessity of running extra generating sets in order to take care of the peaks, and it will, therefore, both enable the total installed horse-power of the power house to be kept to a minimum, and will also keep down the running costs.

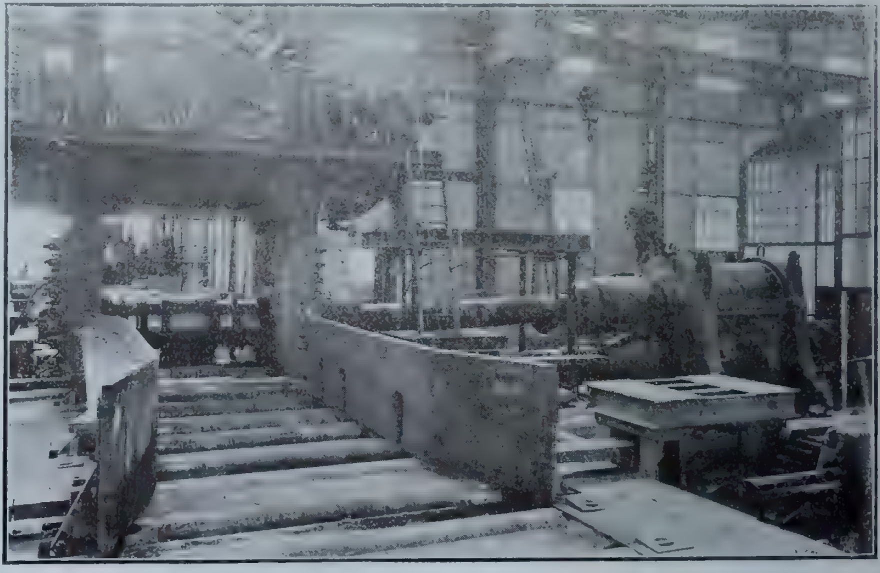

FIG. 8. GENERAL VIEW OF 36 INCH ELECTRICALLY DRIVEN REVERSING BLOOMING MILL AT THE SKINNINGROVE IRON WORKS.

---

*Abstract of paper read recently before the Canadian Society of Civil Engineers, Montreal.

A reversing rolling mill motor, on account of the rapidity with which it has to reverse, must be so designed that its moment of inertia is kept down to a minimum and special precautions must be taken to see that the field of the generator supplying this reversing motor should build up as rapidly as possible. This has been accomplished so successfully that it has been found possible to reverse a large reversing mill motor having rotating parts weighing over 70 tons, 30 or 40 times per minute between a speed of 60 revolutions in one direction and 60 revolutions in the other, when no steel is being rolled. Such tests naturally cannot be made while steel is being rolled because it would be quite impossible with the present type of live roller tables to return the ingots to the mill quickly enough, but such tests are useful in showing the very high rate of acceleration of the mill motor which can be obtained, and as a measure of the handiness of the mill.

FIG. 9. A REVERSING ROLLING MILL D.C. MOTOR AT SKINNINGROVE, 12,000 HORSE-POWER, AT 60 R.P.M.; MAXIMUM SPEED, 120 R.P.M. TOTAL WEIGHT ABOUT 200 TONS. WEIGHT OF REVOLVING PARTS. 72 TONS.

Power Diagram for Reversing Blooming Mill.

Under ordinary conditions the power diagrams for each wind of a hoist are identical and can be calculated with considerable exactitude from the conditions of working, but with a rolling mill the power diagrams for each pass vary very greatly from one another, and cannot be calculated with any accuracy, for the following reasons.

During the earlier passes heavy drafts are taken, but the ingot is quite short, consequently large powers are required for very short times; but as the ingot is gradually rolled out to a bloom of considerable length and reduced in section, the drafts are diminished, as the reduction in area must be kept moderate, otherwise the bloom is damaged by the formation of surface cracks, etc., so that during the last passes the necessary power is not very great, but it is required for a considerable time.

During the first two or three passes the ingot still has its tapered shape and the metal is very spongy in character, so that the powers required are not very heavy and are very irregular. By the time that the last passes are taken the bloom has cooled down considerably and while this cooling increases the specific power required, such drafts are taken that the power required for these remains much less than that for the first passes. In a blooming mill the draft in each pass is regulated by screwing down the rolls, which brings in a personal element, so that it does not follow that the power diagrams for the rolling down of successive ingots resemble one another very closely, and in addition, ingots do not always come to the mill at the same temperature, which also brings in variations in the power diagrams for successive ingots.

It will be seen that in the design of the electrical drive for reversing rolling mills, experience and judgment play a larger part than calculation, and in any case a good margin should always be allowed to insure that the mill is not underpowered. Many tests have been carried out on electrically driven reversing mills to obtain data for the work done in rolling the various sections. Experience has shown, however, that such data should always be accepted with caution, for even where tests are made on the same mill, rolling the same material under conditions which are as similar as it is possible to reproduce in practice, considerable differences are found in the work which has to be done in rolling down the ingots, because the slight differences in the speed of rolling, in the time taken between passes, etc., which cannot be avoided in practice, have a considerable effect on the results obtained.

Action of Flywheel.

There is a great difference between the behavior of the flywheel coupled to the motor generator set used for driving a hoist, and that used for driving a rolling mill. In the case of a hoist where the power diagrams for each successive wind are almost identical, and about an equal period elapses between each wind, the flywheel gives up power during a wind and regains it during the interval, thus serving to equalize the power between individual winds and intervals.

In the case of a rolling mill, and particularly a blooming mill, the flywheel has to do a double duty, because, during the first passes made on an ingot, the mill motor has to give a large power for a very short time as the ingot is short, so that the energy consumption during the earlier passes is much less than the energy consumption during the later passes, where, although the power given by the motor is not so great, the ingot has been rolled out to a considerable length, so that a very considerable energy is required per pass. The flywheel, therefore, has to give up energy during the passes and regain it during the interval between passes, and also the flywheel gains energy during the first passes of an ingot and loses energy during the later passes, so that its speed variation has a double period, namely, a short period of about 5 to 10 seconds, corresponding to the partial equalization of power between the pass and interval, and a long period of about 3 minutes corresponding to the equalization of power over the whole time of rolling an ingot.

As the flywheel used in connection with a rolling mill has to equalize the power over a period of three minutes or so, it is usually found that these flywheels are much heavier than those applied to winding engines. The motor generator set for a blooming mill is usually supplied with a flywheel weighing about 40 tons, while a motor generator set provided for a plate mill, or a finishing mill, is generally supplied with a flywheel weighing anything from 60 to 100 tons, depending on the work which has to be done. The motor generator set for supplying hoists or winding engines is generally provided with a flywheel of not more than from 20 to 30 tons. Such flywheels would run at a peripheral speed of about 20,000 ft. per minute, though in some cases this peripheral speed has been considerably increased. A 100-ton wheel running at this speed would have a stored energy of about 300,000,000 foot lbs. or 545,000 horse power seconds, and in falling 20% in speed would give up 108,000,000 foot lbs. or 195,000 horse power seconds. The total work required to roll a 1½ ton ingot to a 4¾ x 4¾ billet is 59,000,000 foot lbs. or 108,000 horse power seconds.

Safety Devices.

The safety devices provided for an electrically driven rolling mill are of a much simpler character than those provided for a hoist, because it is not necescary to provide against the possibility of an overwind or the loaded cage falling to the bottom of the shaft due to the failure of the electric power. It is only necessary to protect the electrical plant and the mill itself against careless handling.

Shell couplings are usually provided to couple the pinion wobblers to the leading spindles to prevent the motor or pinions being shifted from their bedplate by axial thrust due to a broken roll. This feature is usually also introduced into well designed steam driven mills. A circuit breaker is provided in the main circuit between the generator of the motor generator set and the mill motor to cut off the power from the motor in case, through carelessness, an attempt is made to roll a cold ingot, or too great a draft is taken on an ingot, imposing a greater strain on the motor and mill than they were designed for.

The circuit breaker is a protection against broken rolls as well as against damaging the motor, and it must be remembered that many rolls, especially the bottom roll, have a very small factor of safety. Such a circuit breaker would be most objectionable if used with a hoist, as only the prompt application of the brakes would prevent the cage falling in the shaft when the breaker opened, but with a mill, when the circuit breaker acts the motor merely comes promptly to a standstill, and if there is an ingot between the rolls, the mill can be reversed, the circuit breaker put in, the ingot run out of the mill again, and no damage is done. This circuit breaker can either be operated instantaneously by a maximum current cut-out in the main circuit or else opened by a lever under the control of the driver. In the latter case, the field currents in the generator and motor field are reduced to zero before the circuit breaker operates; in practice this hand lever is seldom used.

During the latter passes, when the ingot has been rolled out to a bloom of considerable length, there is time to accelerate the mill to a much higher speed than is possible when rolling a comparatively short ingot, and this is desirable in order to get the work done as quickly as possible, while, as the section has become much reduced and the draft is small, a relatively small turning moment is required. The mill motor is of course accelerated to the maximum speed at which full turning moment is required by increasing the field of the variable voltage generator. The most convenient way of obtaining the additional speed without increasing the size and capital cost of the plant is by decreasing the mill motor field, though of course at the expense of reducing the possible turning moment, which decreases at a faster rate than the speed increases, but which, however, agrees very well with the requirements of the mill. There is always the possibility, however, of too heavy a draft being taken through carelessness when the mill is running at this high speed, causing an overload against which the circuit breaker would not offer proper protection. To prevent this, a relay is provided, which, when it operates, strengthens the motor field to its full value and reduces the motor speed to the maximum at which it can exert its maximum turning moment, thus both reducing the overload and putting the motor in a better position to meet it; but if the overload be still too great for the motor, the circuit breaker will open.

The purpose of the flywheel coupled to the motor generator set, as mentioned above, is to insure that the rolling mill plant takes an average steady power from the power station irrespective of any fluctuations in power the mill may require, but the value of the average steady power depends on the work that the mill is doing, i.e., the output and the section that is being rolled. If the regulating mechanism be set for the maximum average steady power, corresponding to the heaviest work that is done in the mill, and then much lighter work is done, rolling slabs for plates for instance, the power taken will fluctuate considerably, but will not exceed the value of average power for which the regulator has been set.

As this fluctuation may adversely affect the regulation of the power house, means are provided to enable the regulator to maintain a lower value of average steady power, corresponding to the work that is being done. If the regulator be set for this lower value, and heavy work is again done in the mill, the surplus power will be drawn from the flywheel to give the necessary energy, the speed of the motor generator set will sink lower and lower till at last the flywheel, whose store of energy is proportional to the square of its speed, will not be able to supply enough power to drag the billets through the mill and the mill will stall. To prevent this, two colored lamps are provided on the driver's platform to signal the speed of the flywheel. The first one, the caution signal, lights up when the flywheel is about 22% below full speed, to warn the driver that the average power is inadequate to the work he is doing, and the regulator must be set to a higher value. The second, or danger signal, lights when the flywheel is 30% below speed, and warns the driver that if he goes on he will stall the mill.

A good deal of space in this paper has been devoted to description of safety devices but it should not be considered on this account that there is any inherent risk in using such electrical plant, as the safety devices are to protect the plant against damage due to careless handling. The devices applied to steam hoisting engines, and particularly to steam reversing rolling mill engines, are of a much more rudimentary description, and the safety of such steam plants really depends on the skill and experience of the driver. It should be particularly pointed out that the electrically driven reversing mill does not increase in speed as the ingot passes out of the rolls, while the steam engine, unless carefully handled, will race and run away.

Three-High Mills.

The authors have selected the electrically driven blooming mill as an example, and space unfortunately does not permit the discussion of the modification of the Ward-Leonard system to suit the requirements of plate mills and finishing mills. It is, however, important to mention that there is an increasing tendency in Europe to use the Ward-Leonard system for the driving of three high finishing mills, instead of a continuous running motor and flywheel coupled to the mill. The reason for this is that the Ward-Leonard system enables a much greater output to be obtained from the mill, because the bars may be entered at a low enough speed to prevent damage being done, and, as soon as the rolls have gripped the bar, the speed is run up to a maximum and diminished again so that the bar leaves the rolls at a reasonably low speed.

As a 100-lb. rail rolled from a 4½-ton ingot finishes about 90 ft. long and bulb angles and channel often finish 200 ft. long, the saving in time which may be effected can be appreciated, and as this enables the material to be finished much hotter, the work done in rolling, and consequently the cost of power, and reduced. Where a three-high mill is driven on the Ward-Leonard system it is found that there are far fewer broken rolls than when it is coupled to a continuous running motor and flywheel. These advantages are found in Europe to outweigh the increased capital cost of the plant.

REFRIGERATION DEPARTMENT

ECONOMY IN INSULATING PIPING IN ICE PLANTS.

By Geo. F. Becker, Chicago.

BEFORE going into details on the subject of insulation for piping, etc., I want to say a few things about the laying out of pipe lines that are to be covered, because it is in line with the obect of this paper, viz: economy.

It is very frequently the case that insufficient space is allowed around pipes to permit the application of insulating materials of the desired thickness. The result is double the labor cost, and, very often, the insulating material has to be cut away, which is detrimental to its efficiency and also to its life. This can be avoided by the proper arrangement of piping, which costs no more, cuts down the cost of insulation and increases the efficiency.

About twenty-five years ago, it was no easy matter to convince a steam user of the value of insulation. Boiler and engine builders have done much to economize in fuel consumption, manufacturers of insulating materials have made extensive improvements in coverings to produce the highest grade of efficiency combined with durability, so that to-day heat and cold insulating materials are in general use in almost every plant and the cost of running a plant can be cut to a possible minimum.

Object of Insulation.

The object of insulating radiating surfaces is to convey the energy from the boiler to engine or to its destination with a minimum loss of temperature. Where steam boilers and pipes and other surfaces are exposed, condensation rapidly forms, which decreases power, because every time a pound of water condenses after being generated into steam, it represents just so many pounds of water uselessly evaporated in the boiler on which fuel has already been consumed. This condensation can be almost entirely eliminated by the use of proper insulation and the result is more power per unit or pound of coal consumed, also saving of wear and tear on engine, because excessive condensation in cylinders is not alone dangerous but decreases the power which drives the engine.

To determine the loss of fuel through radiation is a simple matter. It is, however, necessary to know the steam pressure and its temperature, and the loss in B.T.U. per minute per degree of difference. The following table will give you this:

Steam pressure:	Temp.	Loss per min.
Hot Water	175 Deg.	4.5
Hot Water	200 Deg.	5.5
5 lbs.	227 Deg.	7
10 lbs.	239 Deg.	7.5
50 lbs.	297 Deg.	10
75 lbs.	319 Deg.	11
100 lbs.	337 Deg.	12
125 lbs.	352 Deg.	13
150 lbs.	365 Deg.	13.5
175 lbs.	377 Deg.	14
225 lbs.	397 Deg.	15
250 lbs.	406 Deg.	15.5

The next important thing to know is the value of your coal. The units of different coals will vary from 8,000 to 12,000 B.T.U. There is a loss, however, on account of insufficient combustion or other reasons, of a goodly percentage, and a conservative estimate is, in net efficiency, 10,000 B.T.U. per pound. With this information at hand, and the number of square feet of surface to be covered with the price you pay for your coal, you can quite easily figure out what you are losing on account of uninsulated heated surfaces by radiation for any given length of time with the following formula:

Multiply the number of square feet of radiating surface by the unit loss per minute according to what steam pressure you are using (as shown in the above table). Multiply this by 60, representing the number of minutes per hour, by the number of hours which the plant runs per day, and by the number of days which the plant runs per year. This will give you the number of units per year. Divide this by 10,000 (the heat units a pound of coal will liberate) and this divided by 2,000 (representing the number of pounds in a ton of coal) will give the number of tons. This multiplied by the price you are paying per ton for coal will give the loss in dollars and cents.

Obviating the Radiation Loss.

Now that you know what your losses are per year, you naturally wish to know what it is possible to save of this loss, therefore, it is only fair to assume that the best insulation will bring the best results. Various material tests have been made by George Barrus, who is very well known; also by Professor Norton of the Massachusetts Institute of Technology. Both have a reputation of high authority on testing of insulating materials. The latter gives the following insulating values for popular brands:

High Pressure.

Asbesto-Sponge Felted covering will save 85 per cent.

85 per cent. Magnesia Coverings will save 83 per cent.

Low Pressure.

Asbestocel Covering will save 77 per cent.

Air Cell Coverings will save 74 per cent.

Moulded Coverings will save 70 per cent.

You now have approximately what you can save of your losses; let us therefore study the following illustration as an example.

We will say that the following pipes are uncovered:

100 ft. of 1 in.
100 ft. of 1½-inch.
100 feet of 2-inch.
100 feet of 2½-inch.
100 feet of 3-inch.
100 feet of 3½-inch.
100 feet of 4-inch.
100 feet of 4½-inch.
100 feet of 5-inch.

This represents a total of 900 lineal feet of pipe, having a radiating surface of 812 square feet; and we will say that the steam pressure is 150 lbs. You are operating 300 days per year, and you are paying $3 per ton of coal. In accordance with the table given the units lost per minute are 13.5.

$$\left\{\frac{812 \times 13.5 \times 60 \times 10 \times 300}{10{,}000} \div 2000\right\} \times 3.00 = \$294 \text{ loss.}$$

By comparing this with the cost of covering for the 900 lineal feet of pipe, the return on the investment can be arrived at. The list price on the measurements given in accordance with the standard pipe covering list, is $526, for 1 in. thick covering. The approximate discount on asbesto-sponge felted covering which includes its application, is approximately 40 per cent. from the above, so that your net cost for insulation would be $255.60; and in accordance with Prof. Norton's tests you can save 85% of the $294, which equals $250,—your net saving per year by the use of covering. Compare this with the cost of covering, and it distinctly shows that a good insulation will save its original cost the first year. The next essential point is durability. If such an insulation will last an indefinite period without loss of efficiency, it will save a clear $250 for many years to come in the consumption of fuel.

This shows conclusively that insulation is a big factor for economy in a plant. From the tables given, it becomes an easy matter for anyone to estimate his losses and the figures will vary in accordance with what you are paying for coal, and if you are operating your plant more than 10 hours per day, and more than 300 days per year, this will naturally increase the saving. It is also essential to cover the exposed parts of boilers, water heaters, feed water lines and exhaust lines. The latter especially if the exhaust is regenerated into steam.

Cold Pipes.

In regard to cold pipe covering, all the various materials on the market are for all practical purposes the equivalent in insulating efficiency. A comparison between the various materials is therefore of no great importance, and it resolves itself into the question of first cost and life. The first important thing is to have the insulating material properly applied. All joints practically should be made air tight to guard against possible leaks. If this be not done, no matter what covering is used, frost forms between the surface of the pipe and the insulating material, which has a tendency to pry off the latter. This is also the case where covering is not of sufficient thickness, and, in such cases it is absolutely impossible to make repairs to such coverings, but a considerable quantity has to be removed and replaced with new material. It is possible to apply insulating material especially adapted for covering cold pipes so that they will give the desired results, but greater care has always got to be taken than is necessary with the application of heat insulation materials. For instance, on cork covering, the joints run straight from the outside of the insulation to the pipe and unless these joints are properly cemented, or the cork material is not thick enough to withstand the temperature, such troubles as before said are likely to occur.

The two most popular insulating materials for covering ice pipe are cork and hair felt. The latter material is very often combined with a sectional covering over hair felt, composed of waterproof materials. Hair felt coverings are always applied in more than one layer and the joints between the different layers carefully broken. These layers of hair felt, or combination covering as stated before, are applied with hot asphalt in connection with water-proof insulating felts with which the joints are carefully sealed, and the same material is applied between the different layers. In such a construction, there is less chance for a leak. I can only repeat that the correct application of any and all materials suitable for cold pipes is most essential.

Another important item before commencing the application of any and all materials suitable for cold pipes coated with ice is to thoroughly remove all frost and ice from the surfaces that are to be covered. This can be done with hot water, if convenient, but only sufficient ice or frost should be removed ahead of the insulation to prevent this formation coming back on the pipe, that is, when the pipe is under service. It is possible with the use of a piece of waste dipped in oil and wiped over the pipe surface where ice has been removed to prevent the frost from coming back on to the pipe quickly. Better results from insulating materials are obtained by shutting down the plant until the insulation has been applied.

The reasons for covering cold pipes are the same as apply to pipes radiating heat, viz.: economy, in both fuel and machinery, and it is imperative that all exposed surfaces that radiate or absorb heat are insulated in an ice making plant, if you wish to cut down the cost of your product. From uncovered cold pipes, especially when the temperature in the room is somewhat high, there is a constant dripping of water which is not alone a nuisance but very often destructive, and, in order to accomplish the highest efficiency, it is necessary that brine lines, suction lines, liquid lines, headers, accumulators, brine coolers, separators, traps and purifiers be well and sufficiently insulated.—From a paper read befor the Illinois Ice Dealers' Association.

DETERIORATION OF AMMONIA IN COMPRESSION MACHINES.

By A. H. Hutchinson.

It is said by some, if not by all ammonia manufacturers, that it is not possible for deterioration to take place in a compression machine; but most of us know that "foul gases" accumulate in the condenser and must be blown out occasionally, and we also know that there are ammonia losses which cannot be accounted for by leaks, so there must be losses due to deterioration from some cause or other. Personally, I have always taken the ground that there were but two causes for loss of ammonia.

Whenever called upon to investigate the loss of ammonia the first thing I look for is loss through leakage. Quite frequently this solves the trouble, because there are many men running machines who do not appreciate the fact that several small leaks equal one large one, and that leakage of ammonia means increased cost of production, so that the first remedy, and, in my opinion, the most important, is to stop the leaks.

The second loss is that of high pressures. These mean high temperatures. On several plants I have been able to reduce ammonia losses by reducing the suction temperatures, thus decreasing the discharge temperature. The following are some causes of high pressure:

(a).—Warm water. Some times this pressure can be reduced by using a recooler for the liquid as it leaves the condenser, using the condenser water on this re-cooler before it goes to the condenser proper. Sometimes more water will accomplish the desired results.

(b).—Short condenser surface. We are quite apt to try to squeeze a ton or two more out of the plant than was originally contemplated, not realizing that every unit of heat the ammonia absorbs in doing its work must be removed by water on the condenser, thus quite frequently an additional coil of condenser would turn the trick.

(c).—Condensers placed in bad location. Keep them as cool as possible, away from hot boiler or engine room, and influence of the hot sun. Give them plenty of air. This will apply to either atmospheric or double pipe.

There are, in my opinion, three things which might cause what is called deterioration:

(a).—Some chemical in the ammonia heated beyond a given point is turned into a permanent gas.

(b).—Some chemical in the ammonia oil being heated beyond a given point is turned into a permanent gas.

(c).—A combination of chemicals in ammonia and oil being heated beyond a given point is turned into a permanent gas.

It is usually considered that ammonia at 900 deg. F. separates into its constituents, nitrogen and hydrogen, and at a lower temperature a partial separation takes place. Some well known authorities say that temperatures should not exceed 300 deg. F., but from my own experience, I should say that temperatures should not exceed 200 deg. F., and even at that, one should be sure that ammonia is pure and that the right kind of oil is used in the ammonia compressor. In other words, this paper could and may be cut to the following:—

Cause:—Excessive heat, impure ammonia or oil, or all three of them.

Remedy:—Lower temperatures, better ammonia or oil, or all three.—From a paper read recently before the Southern Ice Exchange.

THE TRANSMISSION PROBLEM.

THE rivalry between the different methods of power transmission reminds one of a very similar competition between naval gun makers and armor manufacturers. Electric transmission, even in its crude state, found many applications in which it proved superior to the line shaft drive. Makers of line shaft attachments, however, got busy, and produced roller and ball bearings, lubricating devices, etc. Belt makers and chain drive men are improving their products and simplifying the methods of application to reduce the cost and increase the safety of operation.

The motor drive has undisputed sway in many situations, particularly in connection with large machines and those whose use is intermittent. The belt drive still has many advantages in a more or less narrowing sphere and the newer chain drives are establishing themselves in fields where they cannot easily be superseded.

The more recent developments in available means of power transmission have made necessary particular study on the part of those intrusted with the devising of drives for different purposes and conditions. In fact the transmission problem is becoming more important and complex. It is one in which poor judgment may be the cause of very serious loss, and in which on the other hand, well advised installations will effect large savings in overhead expense as well as form a source of much comfort, convenience and satisfaction.

ADVERTISING MISUNDERSTOOD.

AS fire is to the manufacturing processes so is advertising to the commercial side of industry useful, essential and dangerous. It is strange but certainly true that the impression created by an ever present and attractive advertisement will strongly influence the average buyer of machinery in favor of the article thus advocated. He will place the convictions received from the publisher side by side with the results of actual investigation.

Like all other useful means attached to our social economy, this power is sometimes abused or debased to a wrong purpose. About eight years ago there was placed on the market a certain, at the time well-known machine which was introduced, particularly throughout the West, by a most vigorous and well managed advertising campaign. The result is that fully half the middle-sized shops one visits, have at least one of these machines in the attic or the cellar along with the other "has-beens" and their advent and brief existence are now but incidents of memory. This machine could not fulfill the claims set forth for it in the advertisements of its sales agents, and furnishes one of a number of examples that have borne out the statement of one of our greatest teachers of salesmanship, "A judicious and aggressive system of advertising will sell anything."

It must be remembered that an advertisement is a statement made by the man who wishes to sell the machine and that the advertiser is strongly tempted to tell but one side of its story. While statements that are obviously untrue would not be printed by a reputable publisher, still the man who pays for the privilege is entitled to set forth all the peculiar advantages of his product and in such reasonable language as he sees fit.

The purchaser, on the other hand, need not place himself in a position to be defrauded by an advertisement. Reliable manufacturers are satisfied to use the press as a method of introducing their commodities and are willing to demonstrate the value of their products. All others have no place in connection with a business that is run upon careful conservative lines.

Precocious advertising in itself is seldom the real reason for the non-realization of the qualities expected of a new machine. Cheapness of the appliance, and lack of mechanical judgment on the part of the buyer are often the culprits whose sins are charged to misrepresentation.

When machines are bought which do not fulfill the buyers' idea of their necessary qualifications, it should sound a warning note for the manager. The buying department is in the hands of incompetent persons.

THE OPERATORS' VIEWPOINT

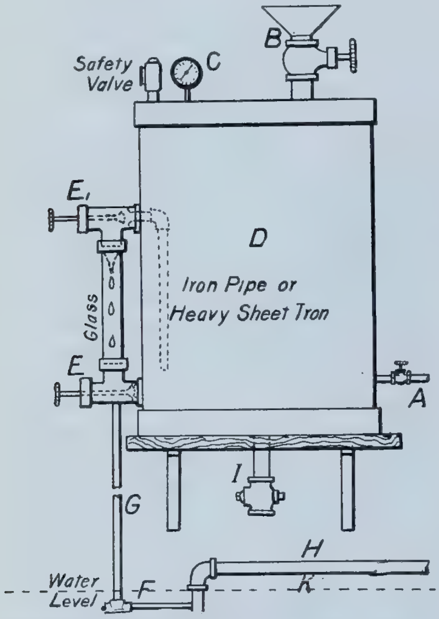
Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

COMPOUND FEEDER WITH NEW POINTS.

By J. E. Noble.

MANY compound feeders have been featured in The Power House at different times, but the one herein described contains one or two new suggestions.

The tank piece (D) may be of large-sized iron pipe, or heavy sheet galvanized iron strongly riveted and soldered, may be used if care be exercised in keeping the pressure well within its capacity. The details consist of a low pressure steam gauge (C), a funnel (B) used to fill the tank (D), a ⅜-in. steam pipe (A) from the boiler, and a stop-cock (I) used for emptying. The whole is placed upon a shelf, as shown. The pump suction pipe is shown at (H), while (K) represents the lowest water level of the supply tank. Fittings (E) and (E_1) were taken from an old sight-feed lubricator. The cock (E) never having to be opened, serves to support the glass. The feed regulation is all accomplished by the cock (E_1).



COMPOUND FEEDER WITH NEW POINTS.

The operation is as follows:—Close all valves except the funnel. Fill the tank with liquid compound and close the funnel valve. Open the valve (A) slightly until a pound or two of pressure is registered by the gauge. Start the feed pump and open the valve (E_1) a little, observing at the same time the speed with which the compound feeds and regulate accordingly. The steam entering at (A) will also serve to keep the solution agitated.

When the mixture becomes weak, draw off some water at (I) and add more compound. At (F) is shown an open tee fitted to the pipe (G) in such a way that if the valve (E_1) be left open and the pump stopped, an overflow will be provided for the excess compound. Normally the pump will draw in the compound along with the water as fast as it is fed.

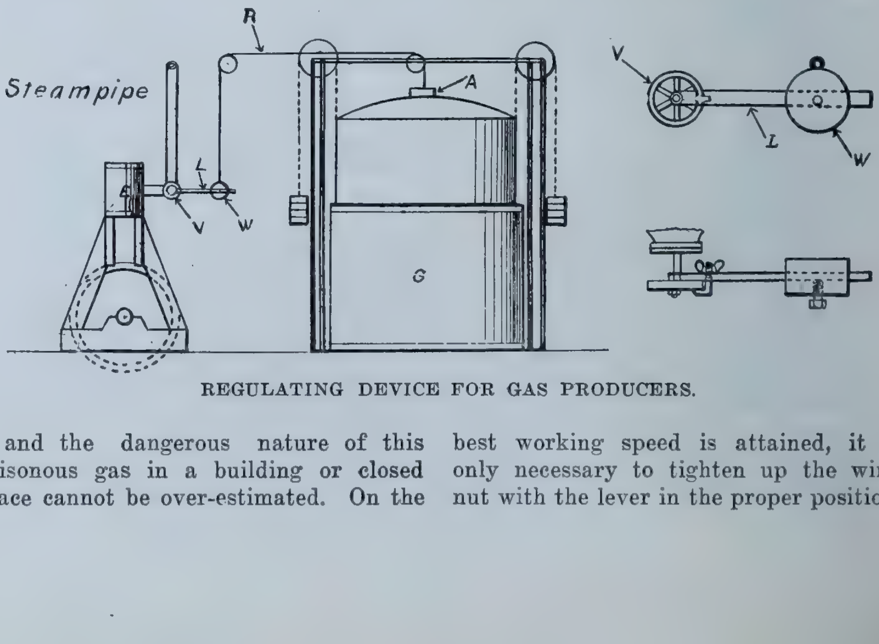
REGULATING DEVICE FOR GAS PRODUCERS.

By R. Bell.

IN connection with gas plants using pressure producers, it is necessary to regulate the speed of the blowers by some means so that the producers supply approximately the amount of gas required by the engines. If this be not done automatically, a constant watch must be kept on the gasometer to prevent it getting too high or too low, especially when a fluctuating load is being carried. If the holder should rise too high, the gas will blow out beneath it and the dangerous nature of this poisonous gas in a building or closed space cannot be over-estimated. On the other hand, I have seen the top of a large gasometer crushed in by the suction of an engine when allowed to go down to the bottom. The accompanying sketch illustrates an extremely simple method of regulation which has been used with great success.

In the above arrangement of the gasometer and blower engine, a lever (L) is attached to the steam valve (V). This lever is connected through the flexible wire rope (R) to a weight (A) on the tank as shown. The counterweight (W) is lighter than (A) but is sufficient to overcome the friction of the valve spindle packing and keep the rope (R) tight. As the holder goes down with a heavy draft of gas, the lever (L) rises, opening the throttle and speeding up the blower engine. Likewise, if the holder rises, the steam is cut off and the blower slows down. The weight (A) is not fastened rigidly to the holder so that there is no danger of breaking the rope by an excessive fall of the gasometer, the weight (A) simply remaining suspended by the cord.

In the second half of the figure is shown the means of fastening the lever to the hand wheel. A hole is drilled in the end of the lever for the valve spindle and another to take the hook bolt clamp as shown. When starting up or slowing down the engine, the lever is disengaged by loosening the wing nut and opening or closing the valve by hand. When the best working speed is attained, it is only necessary to tighten up the wing nut with the lever in the proper position.



REGULATING DEVICE FOR GAS PRODUCERS.

GAS ENGINE TROUBLES.

By W. Stanford.

I WAS interested to read Mr. Grey's query on the above and Mr. Westwood's reply thereto, and would like, if your space permits, to offer a few suggestions. Although not an expert, I have had a good deal of experience with high speed vertical gas engines in England.

The "pounding" that Mr. Grey mentions as occurring at intervals, and which pulls up the engine, is nearly always due to pre-ignition. This was a great trouble to us in our early engines. We found it to be due to too much oil getting past the rings and carbonizing on the top of the piston, and when under full load becoming incandescent. This ignited the charge very early, some 45 degs. in advance of normal, and, of course, shut down the engine in a minute or so. The cure for this trouble lay in two directions, the first being to cut down the amount of oil supplied to the cylinders, and the second to procure a suitable oil. In the engines to which I refer we had seven rings, five at the top and two at the bottom, the duty of the latter being to scrape off the excess of oil thrown up by the connecting rod. This alone was not sufficient if the oil were of too heavy a body.

Not knowing the size of Mr. Grey's engine, I cannot say whether the consumption is heavy or not, but a 200 continuous h.p. engine should not use more than three pints per day of ten hours. Contributory causes may be dirty gas and ineffective cooling, but these come round to the same thing in the end.

I should like to hear further from Mr. Grey in reference to the horse power and the kind of fuel he is using, also whether the lubrication is splash or force.

◆

ENGINEERS SHOULD STUDY COST ACCOUNTING.

By W. W. Pullman.

IN these days when saving and economy are being forced to the front in every line of business it should be to the interests of all engineers to have at least a fair knowledge of systematic cost accounting. Competition everywhere is getting more keen day by day, and manufacturers and owners of plants are looking closely into the question of costs, and where should they naturally investigate more closely than at the power plant, which supplies energy to their establishment. To the manufacturer or plant owner who is on the alert along these lines, the engineer who can render an intelligent and satisfactory account of the cost of running his department will most certainly commend himself for favorable consideration.

Another phase of the question, and one of great importance, is the fact that all over the country isolated steam plants are being replaced by hydro-electric power or power derived from a central station. Sometimes these changes are in the interests of the power user, sometimes they are not. The municipality or company who have power to sell usually have experts on the job, and can show the manufacturer to his satisfaction that they can supply him with energy at a much cheaper rate than he is making it, and there is probably no one sufficiently versed in the conditions of his own power house to give him the exact data in order to refute the assertions. As a consequence, he accepts the offer of central power, whether it be to his advantage or otherwise, and the engineer loses his job.

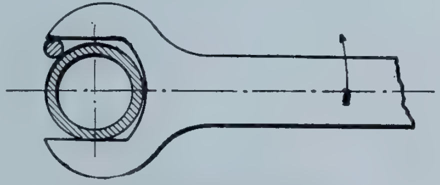
Now, had this engineer been able to have gone intelligently into the matter and demonstrated that, taking all things into consideration, their own production of power was cheapest, he would not only have rendered a service to his employer, but would have retained his position at perhaps increased remuneration.

◆

USEFUL WRENCH KINK.

By G. G. Jackson.

THE sketch shows a simple and effective method of turning a piece of pipe or other round material with an ordinary solid wrench. This is not a new wrinkle by any means, but it will save a great many steps when a pipe wrench is not at hand. Simply place a piece of a small round file between the pipe and wrench as shown and turn in the direction that will tend to jam it in more tightly as the power is applied.



USEFUL WRENCH KINK.

The scheme will not work satisfactorily unless the jaws of the wrench are fairly new and square.

◆

FIGURED OUT.

By. H. W. Benton.

A STUDY of the sketch, and its description as given by R. McLaren on page 132 of April issue of **The Power House**, has sent several lines of thought through my mind. If the designer of this "bag-retarder" has actually been examined and awarded a certificate as a qualified engineer, there is something wrong either with the law or with its application. If there be anywhere in the Dominion of Canada such an outfit in operation, then I am sure it is operated without insurance. I do not know of any boiler insurance company that would allow such a condition to exist. If then the boiler is operated without insurance, where is the factory inspector or the Government boiler inspector that they have not got next to the condition and forced the owners to have it corrected. Personally I do not consider the condition extremely dangerous, that is, I do not consider the boiler liable to explode at any moment as a result of the defect, but it is liable at any moment to give a fireman a very bad scalding; in fact I would positively refuse to operate such an outfit.

There is only one safe and proper way to correct this defect, and that is to cut out the defective material and have a patch riveted on the inside of the shell by a competent boiler maker, and to have the work inspected and passed by the Provincial Government inspector, insurance inspector, or both.

Reason for the "Bag" Formation.

There is a reason for the formation of this bag in the first place. The boiler has been dirty, and the dirt has lodged on the metal where the bag formed. The dirt has kept the water away from the metal; consequently the metal became overheated and the pressure inside the boiler forced the metal out. Once the bag is formed it is impossible to keep mud, scale, etc., from collecting there and consequently the bag will continue to enlarge until a hole is burnt through. The water will then get into the fire and a repair in consequence will become absolutely necessary. In this particular case, however, the engineer has done the boiler maker out of a job, and the expense of the "cure" is only a fraction of the cost of the boiler maker's method, but it is in the same order as all quack medicine; mighty dear stuff in the end, for what this engineer thinks he has, he has not.

Roast for the Engineer.

Mr. McLaren states that the engineer explained that, by opening the valve occasionally, steam was thus allowed to blow through and created such a disturbance in the bag that all mud and undesirable material was blown out. This is about as absurd and impractical an explanation as I have seen placed before the readers of a technical magazine. The fact that a man called an engineer, would install such an apparatus, and then offer such a ridiculous explanation for its justification and accept it himself, is surely good evidence that he should be back in the boiler house, passing coal, instead of in charge of any plant, and further that the laws or combination of laws and conditions that certify such a man as an engineer are a disgrace to the intelligence of all persons interested.

There is in my mind no doubt but that the connection and its use as described by Mr. McLaren does some good; because when the valve is closed steam condenses in the pipe above the valve and fills the riser with water, hence the water in the pipe is higher than the water level in the boiler, and as soon as the valve is opened the water in the pipe will feed into the boiler through the pipe connection into the "bag," until the water in the pipe is level with the water in the boiler. Since the water that can be stored in this pipe above water level of boiler is very small, it follows that the current or circulation that is created by opening the valve is very slight and hence if the engineer should forget or neglect to open the valve frequently, or if mud should collect rapidly in the "bag," there would not be difference of pressure enough to overcome much of a resistance and the scheme would not work. Once the circulation became choked up it would only be a short time until the pipes would burn out and drop out of the bag thus allowing the pressure inside the boiler to force the mud out and of course the water would then follow with such force as to drown out the fire with the attendant possibility of seriously scalding whoever might be near at the time.

I think that drilling the hole into the centre of the "bag" has offset any danger of the sheet tearing, and any enlargement of the bag or overheating would simply release the grip of the threads on the pipe nipple and thus release the connection and allow the water out onto the fire as before stated. I do not, therefore, consider the boiler liable to explode from this defect.

The scheme could easily have been improved by carrying the steam connection up as high as possible before coming down to the valve, say 30 feet if possible, and then fitting a tee instead of the ell under the valve with nipple and valve and drain line to sewer, so that all mud and settlement could be blown out of the "bag" at regular periods as found necessary.

I simply make this statement to show that the engineer did not give the situation any study or else he did not understand the conditions, otherwise he would not have been so boastful of a half-done, half-studied piece of work that in itself speaks so clearly of his ignorance of steam engineering.

The engineer "figures" that he blows the mud out of that "bag" with steam and puts a valve in the line with which to control the steam. **Steam never gets near that "bag,"** and the method of using the valve is his only chance to make the thing work, but it works very different from what he thinks it does.

Suppose no valve was there or the valve were left open all the time: water (in the pipe through the furnace) would be evaporated and would rise up the pipe at front of boiler into steam space and more water would flow down into the pipe through the "bag" to keep up supply of water being evaporated. Thus there would be a circulation of water down through the "bag" into the pipe; this would tend to draw mud into the "bag" and it would only be a short time until pipe and "bag" both would be choked up.

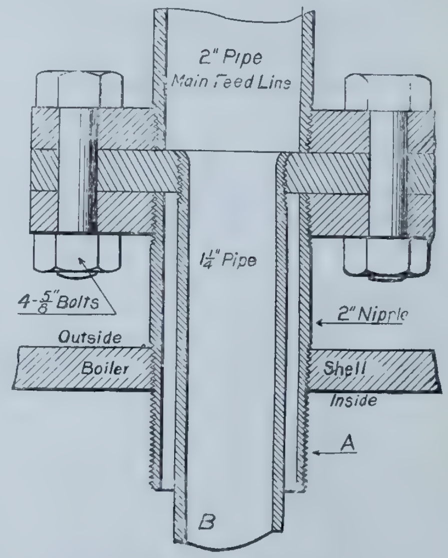
Mr. McLaren deserves a vote of thanks for having this man-trap advertised, and the government inspector ought to be posted as to where this boiler is, so that the affair can be corrected by someone "capable to achieve the desired end of **protection.**" That **engineer** should be saved from himself!

◆

A FEED PIPE KINK.

By F. Cunningham.

OUR boilers are of the horizontal, return-tubular type, and for a long time we had considerable trouble from leakage at the point where the feed pipe entered the shell. No matter how tight the pipe was screwed in, leakage always commenced as soon as the feed pump was started up, due to the difference in temperature between the feed water and the pipe, causing the latter to contract and allow steam to leak past the threads.



A FEED PIPE KINK.

To overcome the difficulty, the feed line was modified as shown in the sketch. A 2-inch nipple was fitted with a flange and screwed into the boiler until it projected about 1½ inches inside. The feed pipe was cut and fitted with a similar flange, and between these two flanges a third was sandwiched which carried the internal feed pipe B. The latter was made of 1¼-inch pipe to allow a steam space between it and the nipple, and thus keep the nipple at a constant temperature.

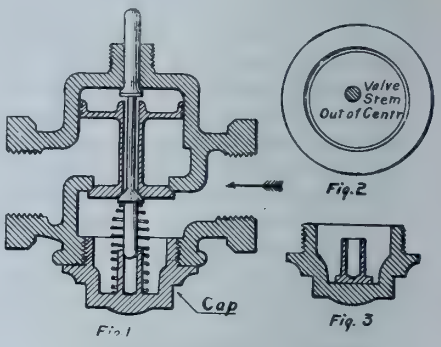
This device proved entirely satisfactory, and we have had no trouble with leakage since it was adopted.

◆

WHISTLE VALVE TROUBLE.

By W. B. Henry.

SOME time ago when taking charge of a plant I was told that the whistle valve was no good, and that the whistle itself was blown by a man opening and closing a 3-in. globe valve while standing on a ladder; the valve being about 14 ft. above the floor.



WHISTLE VALVE TROUBLE.

This particular whistle valve, according to report "was not built properly"—it was "out of line," or had some such defect. All effort, however, to make it work had failed absolutely.

The valve was of the balanced whistle type, and was new, that is, it had been installed but never had worked. It was the product of a very reliable firm, and I could not understand why a new valve of their make could be wrong. An examination was made and sure enough the valve was out of line. With the cap, Fig. 2, removed and the valve pressed firmly to its seat, the valve stem was out of centre just the width of itself as shown in Fig. 2. The valve stem guide in the valve body cap was cast solid with the cap and machined exactly central with the cap; hence the valve stem should be central with the threads in the body where the cap screws on. By screwing on this cap, the valve was held slightly to one side of its seat and could not possibly get there. The valve could be pushed open, but not freely, and if pushed wide open would stick altogether, the spring not being strong enough to force it back again on account of the misalignment of the parts.

The defect was easily overcome, as what follows, together with the illustrations makes abundantly clear. I had the valve cap put in a lathe, and turned out the valve stem guide, leaving the inside of the cap turned smooth and flat. In place of the solid guide I had a self-aligning guide made of the same size as the solid guide, except that on the bottom end a flange was left large enough to have the spring rest, so as to keep this guide pressed firmly against the end of the cap. By this method the valve stem guide moves on the inside of the cap to accommodate the misalignment of the valve parts.

HOISTING AND PORTABLE ENGINEERS ORGANIZE.

WHAT will in future be known as the Queen City Local No. 15, Canadian Association of Stationary, Hoisting and Portable Engineers was duly organized in Toronto on April 27. The objects and composition of the Association are as follows:—

The elevation and maintenance of the rights of the Canadian hoisting and portable engineers, and their recognition by such business interests as their calling warrants.

The Association shall be composed of stationary and hoisting engineers of good moral character, and who are Canadian citizens, and its meetings shall be devoted to the educational, professional and social welfare of its members.

The following officers were appointed and installed:—

President—J. D. Provost.
Vice-Pres.—P. J. Murphy.
Fin. Sec'y—O. J. Hartley.
Rec.-Sec'y—M. Clark.
Treasurer—H. Joyce.
Conductor—A. Warner.
Doorkeeper—A. Dunn.
Trustees—W. Ball, A. Dunn, F. Allen.

Meetings are held in the Victoria Hall, Queen street East, on the first and third Wednesday of each month.

HOW I FIGURE IT OUT?

By John Thorn.

"THE ability to achieve a desired end is more important than passing examinations for certificates." The engineer who wrote the above words in the letter which appeared in the April issue of **The Power House** was right, but surely the freak outfit he described showed no ability, for it certainly will not do the work it is supposed to do, namely, blow the sediment out of a bag in the boiler shell. Furthermore, it is a dangerous outfit.

A moment's thought will show that the steam pressure is less than the pressure it is expected to blow against. There is the steam pressure above the water plus the pressure of the height of the water in the boiler at the hole in the bag. A certain amount of water of condensation will collect in the pipe above the valve and, when it is opened, some of it will run down and enter the boiler until the water in the pipe is at the same level as the water in the boiler. The pipe crossing the furnace above the fire will soon burn out as the heat will force the water out of it, either into the boiler or up the pipe (when the valve is opened for a few seconds at a time). It gets so much heat that a greater pressure will be momentarily generated in it. During the few seconds it is practically empty it will thus become overheated, and as the water rushes back into it a break will likely occur, caused by rapid contraction.

This is the reason feed water pipes cannot be installed in boiler furnaces. To be a success a continuous flow of water must circulate through the pipe. A much better arrangement would be to run the pipe from the bag to a sewer and blow it out frequently. The only sane and safe thing to do, however, is to drive the bag back or cut it out and put in a hard patch just as soon as possible.

That is what would be called reliable ability and good engineering, but the scheme described is poor ability and mighty bad engineering.

READERS' QUERIES.

Soldered Joints for Steam Coils.—Please explain through your columns why solder will not stand up under steam heat and pressure? A short time ago I ordered some heater pipes, which had begun to leak, to be repaired by brazing. The coil rested on the bottom of a drum, and on account of continual rubbing had been worn so thin that it had cracked, causing so much leakage that the pump could not supply the required water to the boilers. When I called at the shop to inspect the brazing job I found it all plastered up with solder. The man who did the job insisted that the soldered job was strictly good practice and fully as good as brazing for this purpose. My experience having taught me otherwise; as the coil is subjected to 100 pounds pressure, I took the job to another shop, where it was brazed without protest. An expression of opinion is wanted as to whether solder will or will not stand up under average steam pressures, and why.—W. Malloch, Belleville, Ont.

Radiator Condensation for Feed Water.—I am trying to induce my employer to utilize, for boiler feed, condensation from steam pans and radiators. He contends, however, that it is injurious to the boiler, in that it sets up galvanic action, and thus causes pitting. Would you please state through your paper whether this is so or not, as I cannot see it his way.—R. V. A.

Safety Valve Springs.—Will you please answer through your columns the question: "What type of stress is set up in the spring of a safety valve in the act of blowing off?" Mr. Swan, the well-known engineer of the steam plant at Britannia Beach, tells me that three marine engineers with first-class certificates claimed that the stress was tensile, and would not agree that it was entirely torsional. The views of Prof. Short differ in other ways from both of these.

Trade Gossip

J. E. Aldred, president of the Cedar Rapids Co., was in Montreal recently and inspected the development work.

The Olympia Hotel, Winnipeg, Man., is being equipped with a 20-ton Arctic refrigerating plant, which was supplied by the Arctic Ice Machine Co., Canton, Ohio.

The Consumers' Ice Co., Winnipeg, Man., have purchased 11,500 feet of piping for their 3,500 ton ice storage house. from the Arctic Ice Machine Co., Canton, Ohio.

The Dominion Steam Heating Co., Toronto, have submitted an application to the Board of Control for permission to install a central heating system for office buildings, etc.

The Crystal Ice Co., Calgary, Alta., are installing a complete 50-ton Arctic Pownall raw water ice-making system, to be equipped with Arctic-Pownall shell brine coolers and operated by a gas engine.

Humboldt, Sask.—The following contracts have been awarded:—(B), Pump house station, Hanson & Paul, $5,120, and foundations for machinery at $8 per cubic yard; (C), Water tower, G. A. Sisson, $12,000; (D), Water pipes and specials, Canadian Allis-Chalmers Co., Ltd., $40.50 per ton for cast iron pipe, $69.25 per ton for special castings; (E), Hydrants and valves, Canadian Allis-Chalmers Co., Ltd., hydrants $46.20 each, steamer nozzles 75c per inch, sprinkling cranes $56.20 each, gate valves 10-inch $35.30 each; 8-inch, $22.30 each; 6-inch, $14.75 each, valve boxes, $14 each; (N), 12-inch wooden pipe, Pacific Coast Wood Pipe Co., 45c per foot, F.O.B. Humboldt; (P), Sewage pumping station, Flanagan & Murphy, $7,900; (X) Sewage disposal works, Flanagan & Murphy, $16,855, pipe laying $2 per foot. The contract for the pumping machinery was not awarded, but the tenders received averaged about $13,000.

Instruction Course for Power Plant Operators--I.

By M. L. Smith, B.A.Sc.

Throughout the writer's experience as a teacher, he has been continually confronted with the query: "Can you recommend a text book for power plant employees?" This, on account of specialization of the different branches of the work and the fact that most books published deal with methods of particular localities, is practically impossible. This series of articles is intended to supply the need, to set forth the technical points so that firemen and engineers can understand and apply them, and be thereby assisted in passing the various qualifying examinations.

INTRODUCTORY.—The qualifications demanded of a stationary engineer who aspires to reach senior rank in his profession cover such a wide field of knowledge and experience that an attempt to include the whole in a single text is difficult. It is necessary, then, that each subject be treated straight to the point and as briefly as possible, which must be done without sacrificing simplicity and ease of comprehension.

It is impossible to prevent the use of a word occasionally, the meaning of which is not perfectly clear to the reader. In this case, a small dictionary will greatly assist to make the course interesting and instructive. To obtain the greatest benefit it is also necessary to have a knowledge of addition, subtraction multiplication and division, as well as lineal measurement or measure of length, square measure or measures of surface, measures of volume or cubic measure and measures of weight and capacity. The lack of space prevents these subjects being included here, but they can easily be mastered with the help of a schoolboy's arithmetic, costing but a few cents.

A few simple problems will be worked out in connection with each article, and it is suggested that these be carefully studied until the principle used in each is thoroughly understood.

Steam Engine.

Definition.—A steam engine is a machine for the changing of heat into mechanical work in which the working substance is steam or water vapor.

Historical Sketch.

The earliest known type of steam engine was a form of reaction turbine, the same in principle as the Parson's, which is being so generally installed at the present time. This was made by Hero of Alexandria in the year 130 B.C., and consisted of a small, round, flat vessel with bent pipes fitted radially. Steam was admitted through one of the pivots and, by blowing out through the bent tubes, forced tubes and all around in the opposite direction, after the manner of the much used rotary lawn sprinkler. Little was accomplished until the 17th century other than the use of steam to operate fountains and toys. An impulse turbine was devised in 1629 which was merely a small water wheel driven by a jet of steam.

Savary.

The first commercially successful engine was built by Savary in 1698. This was a steam pump built on almost the exact lines of the pulsometer of the present time. Steam was admitted to an oval vessel A, Fig. 1, forcing the water out through the check valve B. When the chamber became empty of water, the steam supply was cut off and the steam in the vessel was condensed by a stream of cold water sprayed upon the outside. The vacuum thus formed caused a fresh supply of water to be sucked up through the valve. D. steam was again turned on and the process repeated.

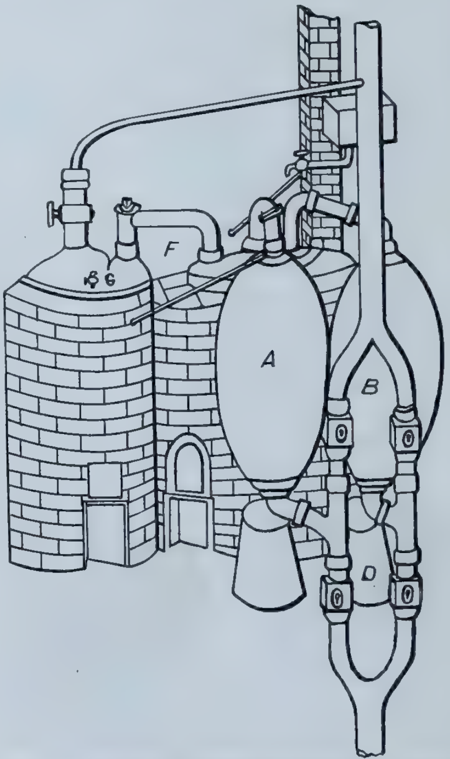


FIG. 1. SAVARY'S PUMPING ENGINE, 1698.

Savary's pumps were built with either one or two chambers very similar to our single and duplex pumps of today, the latter, of course, producing a steadier flow of water. It will be noticed that there are two boilers and furnaces. The one was used to force the feed water into the other. It was first filled with cold water, and by putting a fire under it the water could be forced into the main boiler as desired. A pipe led from the gauge cock to near the bottom of the boiler, so that by opening the cock the operator could tell when the water supply became low.

The height to which water could be pumped depended, of course, upon the steam pressure. Pressures up to 120 and 140 pounds per square inch were carried without safety valves and with boiler and pipe joints made of soft solder and spelter. The most noticeable feature of this engine was the enormous quantity of coal used, being about twenty times that of modern practice. Steam coming into direct contact with cold water and being condensed in the same chamber as used, caused great losses, due to what we now call cylinder condensation.

About this time many attempts were made, principally in France, to produce an internal combustion engine driven by gun powder, but without great success.

Papin.

The next great improvement was made by Dennis Papin in 1690, who put a piston in Savary's engine, Fig. II. This was made of wood, and simply prevented the live steam from pressing directly upon the cold water. Papin seems to have been the first to see the advantages of dry steam. He provided a chamber (D) in the piston to hold a piece of hot iron for the purpose of preventing condensation. Papin also invented the safety valve and the closed air chamber, shown at B.

Newcomen.

In 1705 Newcomen improved the steam engine to the extent shown in Fig. III. Steam entered the cylinder from the boiler, forcing the piston upwards. This was helped by the weight hung on the other end of the beam. The steam in the cylinder was then condensed at first by a stream of water on the outside of the cylinder, but later by a jet of water sprayed inside as shown. The vacuum formed caused the piston to be drawn down and the pump rod attached to the other end of the beam to be raised.

Newcomen's machine was a single-acting engine using very low steam pressures, being worked at times with the manhole of the boiler open. Hence the term "atmospheric engine." The piston was kept covered with water, which not only prevented air leaking past, but by leaking in itself helped to condense the steam.

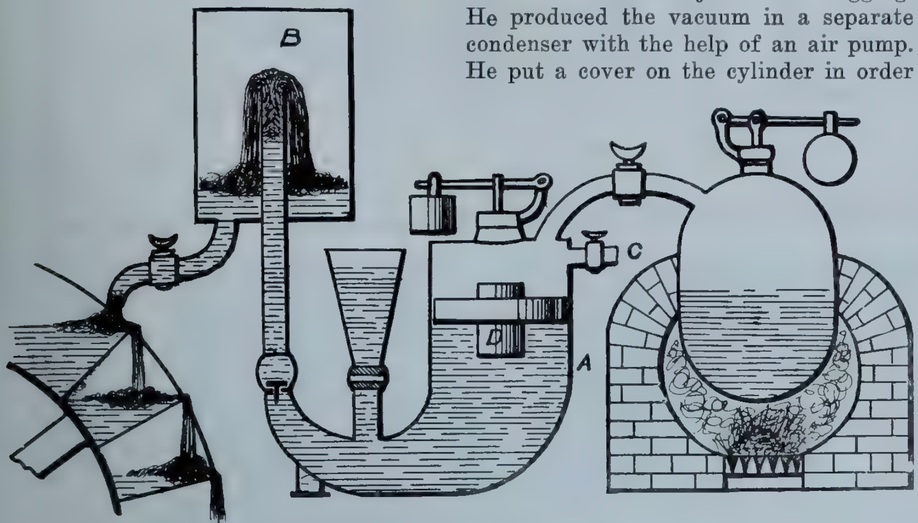

FIG. 2. PAPIN'S PUMPING ENGINE DRIVING WATER WHEEL, 1690. (A), CYLINDER; (C), EXHAUST VALVE; (D), HEATER; (B), AIR CHAMBER.

It is in connection with Newcomen's engine that the story of Humphrey Potter is told. The boy's duty was to operate the valves of an engine at each stroke, but being of an inventive turn of mind, he connected up the valves with cords to the walking beam, thus producing the first automatic valve gear. Newcomen's engine remained practically unchanged for seventy-five years except for some improvements made by John Smeaton. It was used exclusively for pumping water, and, like that of Savary, used a vast amount of coal.

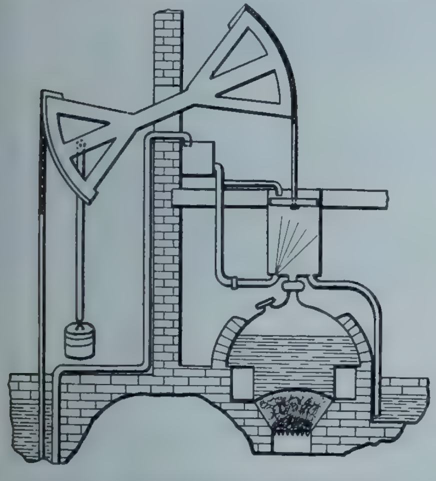

FIG. 3. NEWCOMEN'S ATMOSPHERIC ENGINE, 1705.

James Watt.

By far the greatest improvements to the steam engine were brought about by James Watt, an instrument maker, of Glasgow, who bears much the same relation to the steam engine as Edison does to electricity. While repairing a model of Newcomen's engine, about 1763, he was struck by its enormous loss through condensation in the cylinder. He saw that, to save coal, the cylinder must be kept hot, and to this end added a steam jacket and lagging. He produced the vacuum in a separate condenser with the help of an air pump. He put a cover on the cylinder in order to use steam pressure as well as the suction of a vacuum. The crank being already patented, he devised a gear drive which he called a "sun and planet" motion, and used it until the crank patent expired.

In 1782 Watt brought out a double acting engine in which the steam was used expansively, and from this time forth the steam engine was applied to many other purposes than pumping water. Other inventions of Watt are the throttle valve, the centrifugal governor, the steam engine indicator, and he also settled the value of the horsepower as 33,000 foot pounds.

Throughout his work Watt stuck to low pressures, and fed his boilers through a vertical pipe high enough to allow the water to flow in by its own weight against the boiler pressure.

General Improvements.

The high pressure engine was developed about 1800 by Evans in the United States and Trevithick in England, both of whom used internally fired boilers and devoted their attention to locomotive work. Trevithick was the first to use a steam carriage on a railway. The compound engine was invented in 1781 and greatly improved by Wolf about 1804.

About this time Stephenson began the work that put the locomotive upon a permanent working basis, and in 1829 built the famous engine called the "Rocket," which settled all doubt as to the coming methods of land transportation. This inventor greatly improved the steam blast, built the first tubular boiler, and devised the link motion.

The marine engine in, the meantime, was being developed by Symington, Fulton, Bell and others, and the triple expansion engine became the standard type for marine purposes, but even this has now been largely supplanted by the steam turbine in the hands of C. A. Parsons.

Summary.

Savary invented the pulsometer type of pump.

Papin devised the piston, safety valve, and air chamber.

Newcomen invented the atmospheric engine.

Watt is the inventor of the condenser and air pump, the double acting engine, the use of steam expansively, the throttle valve, centrifugal governor, the indicator, and the horse-power.

Stephenson was the first to use the tubular boiler and the link motion.

* * *

HOW I FIGURE IT OUT?

By W. H. J.

THE device described under the above heading by Robert McLaren in the April number of **The Power House** attracted my attention. Although the steam and water are at the same temperature and pressure, the steam introduced at the bottom of the boiler would doubtless rise in bubbles through the water and thus cause a slight commotion of the water in the "bag." Notwithstanding this, would not a far better result be obtained by piping the "bag" to the delivery line of the feed pump? Of course, I am not suggesting that the whole of the feed should be introduced at this point, but that a pipe should be taken off the main feed line by a "Y" and led to the bulge in the plate. This pipe would, of course, be fitted with a globe valve and check.

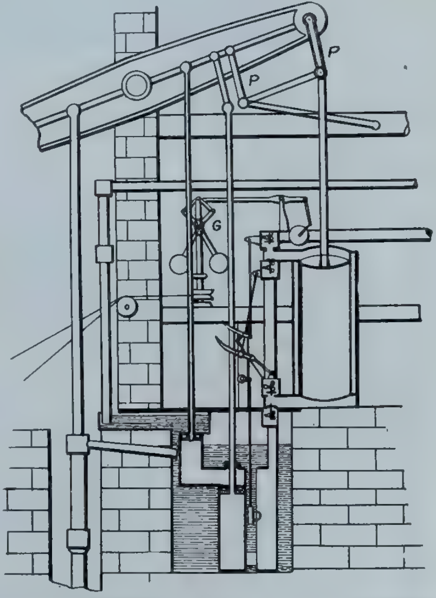

FIG. 4. WATT'S DOUBLE ACTING ENGINE, 1782.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

Question.—A steam boiler 16 feet long and 40 inches in diameter, is made of material ½ inch thick, and carries a pressure of 80 pounds per square inch gauge. What is the stress in the shell-plate?

Answer.—The total pressure tending to disrupt the shell would be the total pressure on the longitudinal cross section, which is $16 \times 12 \times 40 \times 80 = 614400$ pounds.

This pressure is distributed over twice the cross sectional area of the plate, or a surface equal to $16 \times 12 \times 2 \times \frac{1}{2} = 192$ square inches. Stress in shell plate is, therefore, $\frac{614400}{192} = 3{,}200$ lbs. per sq. in.

* * *

Question.—What width of double-ply leather belt would be required to transmit 176 horse-power from a 7-foot pulley at 96 r.p.m.?

Answer.—Using formula

$$w = \frac{H.P. \times 300}{V} \quad \text{In which}$$

w = width of belt in inches.
H.P. = horse-power transmitted.
V = velocity of belt in feet per min.
300 = a constant for double belts.

V = circumference of pulley × r.p.m. or

$$V = \frac{22}{7} \times 7 \times 96 = 2112 \text{ ft. per min.}$$

$$\text{Then } w = \frac{176 \times 300}{2112} = 25 \text{ inches, or}$$

say a 26-inch belt.

* * *

Question.—A motor running at a speed of 600 r.p.m., drives a fan through a counter shaft. A 10 in. pulley on the motor drives to a 28 in. pulley on the countershaft which, in turn drives a 12 in. pulley on the fan from a 56 in. pulley. Find the speed of the fan.

Answer.—Drivers are 10 in. and 56 in.
Driven are 28 in. and 12 in.

Speed of fan, therefore, is

$$\frac{10}{28} \times \frac{56}{12} \times 600 = 1000 \text{ r.p.m.}$$

* * *

Question.—What should be the thickness of a 10 in. cast iron water pipe to carry a steady pressure of 300 pounds per sq. in. Ultimate tensile strength of cast iron 20,000 lbs. per sq. in.

Answer.—Using a factor of safety of 6, the working stress would be $\frac{20{,}000}{6}$

Pressure tending to disrupt pipe is

$$\frac{10 \times 300}{2} = 1500 \text{ pounds.}$$

Area of metal necessary to resist this is $\frac{1500}{20000} \times 6 = .45$ sq. in.

As we are considering a section 1 in. long, the required thickness would therefore be .45 inch.

* * *

Question.—What horse-power boiler would be required for a good Corliss engine of 120 h.p. taking steam at 100 lbs. gauge and with feed water at 200 degs. Fah?

Answer.—An engine of this type would use about 20 pounds of steam per horse-power hour.

One boiler horse-power represents the evaporation of 34.5 pounds of water from and at 212 degs., and to reduce the above conditions to this base the factor of evaporation is used, which for this pressure and feed water temperature is 1.052.

Steam used per hour is $120 \times 20 = 2400$ pounds.

Boiler h.p. required is

$$\frac{2400 \times 1.052}{34.5} = 73.18 \text{ h.p.}$$

* * *

Question.—What would be the weight of water in a cylindrical tank three-quarters filled and of the following dimensions, diameter 20 ft., and height 14 feet.

Answer.—Find volume of ¾ of tank thus:

$$\text{Volume} = \frac{3 \times 22}{4 \times 7} \times 10^2 \times 14 = 3300 \text{ cu.ft.}$$

$$\text{Weight} = 3300 \times 62.5 = 206{,}250 \text{ lbs.}$$

$$\text{or } \frac{206{,}250}{2000} = 103\tfrac{1}{4} \text{ tons.}$$

* * *

Question. — What would be the required diameter of a mild steel piston rod for an engine 24×30 with a maximum steam pressure of 90 pounds per square inch?

Answer.—Maximum load on piston would be area × pressure or,

$$\frac{12^2 \times 22 \times 90}{7} = 40715.1 \text{ pounds.}$$

Allowable working stress is 8,000 pounds per square inch under these conditions.

Area required then is

$$\frac{40715.1}{8000} = 5.0893 \text{ square inches.}$$

Diameter of a shaft of this cross sectional area would be $2\sqrt{a \times \frac{7}{22}} = 2.54$ inches or approximately 2½ inches.

* * *

Question.—Why is it necessary to make the longitudinal seams of a boiler shell twice as strong as the circular seams?

Answer.—Consider a shell 10 inches in diameter sustaining a pressure of 100 pounds per square inch.

Stress on lengthwise seam per inch of length $= \frac{10 \times 100}{20}$ or 500 pounds.

Stress on 1 inch of ring seam is equal to total pressure on shell cross section divided by the length of the seam, or is equal to

$$\frac{3.1416 \times 5^2 \times 100}{10 \times 3.1416} = 250 \text{ pounds.}$$

Which is half that for the longitudinal seam.

* * *

Question.—What would be the approximate mean effective pressure throughout the stroke of a noncondensing engine, the steam pressure being 120 lbs. gauge, the back pressure being 17 lbs (absolute), and the point of real cut off at 1-6 of the stroke.

Answer.—Using formula

$$M.E.P. = \frac{.9P(1+2.3 \log. r)}{r} - .9p$$

In which P = steam pressure absolute or gauge pressure + 14.7 lbs.
r = ratio of expansion.
p = back pressure absolute.
.9 = indicator factor depending on quality or type of the engine. We get

$$\frac{.9 \times 134.7 \times (1+2.3 \times .77815)}{6} - .9 \times 17 =$$

$$\frac{121.23 \times 2.789}{6} - 15.3 = 41 \text{ lbs. sq. in.}$$

Arithmetic for the Machinist and Operative-Engineer

By J. H. Rodgers

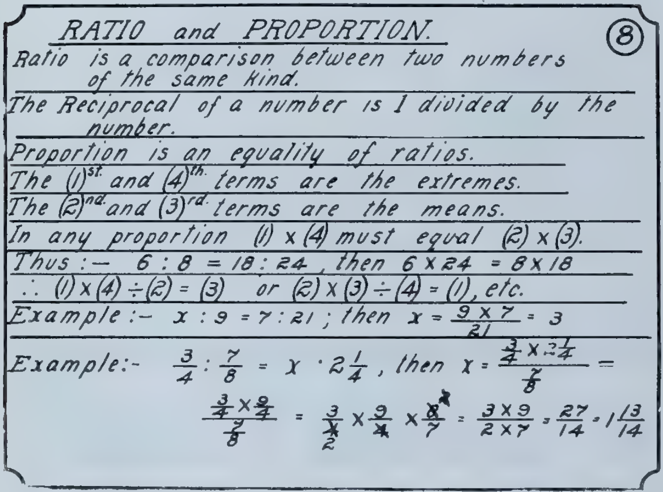
With the further development of this course in arithmetic, it will be found by those who have followed the introductory lessons and profited by them that the various practical applications resulting from the succeeding lessons will be easily observed and their time and labor-saving features so appreciated as to be adopted at every available opportunity.

RATIO AND PROPORTION.

RATIO is the comparison between two numbers of the same denomination, as, 4 is to 8, 120 revolutions is to 180 revolutions, 35 teeth is to 70 teeth; etc. (See Chart 8.) The expression of a ratio is shown in several ways; thus, $3 \div 2$, $3:2$ and $\frac{3}{2}$. That generally used is the second; 3:2, the above ratios being expressed, 4:8, 120 rev.: 180 rev., 35 teeth: 70 teeth, etc. A ratio may be raised to any power, or any root of it may be taken. (See Chart 9).

Proportion (or the rule of three) is one of the most useful sections of mathematics. It is an equality of ratios, indicated by the sign of equality (=). Thus the ratio of 8:6 is equal to the ratio of 24:18, or 8:6=24:18.

Each ratio of a proportion is called a couplet, and each number is called a term. The first and fourth terms are called the extremes, the second and third are known as the means. In any proportion, the product of the means equal the product of the extremes. A direct proportion is one in which both couplets are direct ratios, while an inverse proportion is one which requires one of the couplets to be expressed as an inverse ratio. Such an expression must be changed to a direct proportion by inverting one of the couplets before solution. The principle of all calculations in proportion is that three of the terms are always known; the fourth being required.



RATIO and PROPORTION. ⑧

Ratio is a comparison between two numbers of the same kind.

The Reciprocal of a number is 1 divided by the number.

Proportion is an equality of ratios.

The (1)st. and (4)th. terms are the extremes.

The (2)nd. and (3)rd. terms are the means.

In any proportion (1) x (4) must equal (2) x (3).

Thus :— $6 : 8 = 18 : 24$, then $6 \times 24 = 8 \times 18$

$\therefore (1) \times (4) \div (2) = (3)$ or $(2) \times (3) \div (4) = (1)$, etc.

Example :— $x : 9 = 7 : 21$; then $x = \frac{9 \times 7}{21} = 3$

Example:— $\frac{3}{4} : \frac{7}{8} = x \cdot 2\frac{1}{4}$, then $x = \frac{\frac{3}{4} \times 2\frac{1}{4}}{\frac{7}{8}} = \frac{\frac{3}{4} \times \frac{9}{4}}{\frac{7}{8}} = \frac{3}{\underset{2}{\cancel{4}}} \times \frac{9}{\cancel{4}} \times \frac{\overset{\cancel{2}}{\cancel{8}}}{7} = \frac{3 \times 9}{2 \times 7} = \frac{27}{14} = 1\frac{13}{14}$

ARITHMETIC CHART 8.

The circumferences of two circles vary directly as their diameters, therefore, the circumference of a circle 5 inches in diameter being 15.708 inches; what is the diameter of a circle whose circumference is 23.5 inches?

Expressing the unknown quantity by X, we have

$$5 : x = 15.708 : 23.5,$$

$$\text{Then } X = \frac{5 \times 23.5}{15.708} = 7.48 \text{ inches.}$$

Again, the output of a certain machine being 80 pieces a day; what would be the result if the driving pulley were changed from 15 inches dia. to 18 inches dia.?

$$15 : 18 = 80 : X,$$

$$\text{then } X = \frac{18 \times 80}{15} = \frac{6 \times 16}{1} = 96 \text{ pieces.}$$

In a belt drive, the speed of a certain spindle was 514 revs. per minute. The driving pulleys were 20 in. and 18 in., and the driven pulleys 14 in. and 10 in. diameters. The main shaft has a speed of 200 rev. per minute. Wishing a spindle speed of about 600 rev. per minute, and the only pulleys available being of 20 in. and 12 in. diameter; which one should be used and where, to give the desired result?

The speed of a driven shaft varies directly as the diameter of the driving pulley, or inversely as the diameter of the driven pulley, therefore, the larger the driving pulley, the greater the speed, and vice versa.

Replacing the 18 in. driving pulley with that of 20 in., we get

$$514 : X = 18 : 20$$

$$\text{or } X = \frac{514 \times 20}{18} = \frac{5140}{9} = 571 \text{ revolutions.}$$

Using the 12 in. diameter in place of the 14 in. driven pulley, we have

$$514 : X = 12 : 14 \text{ or } X = \frac{514 \times 14}{12} = \frac{257 \times 7}{3} = \frac{1799}{3} = 599 \text{ revolutions.}$$

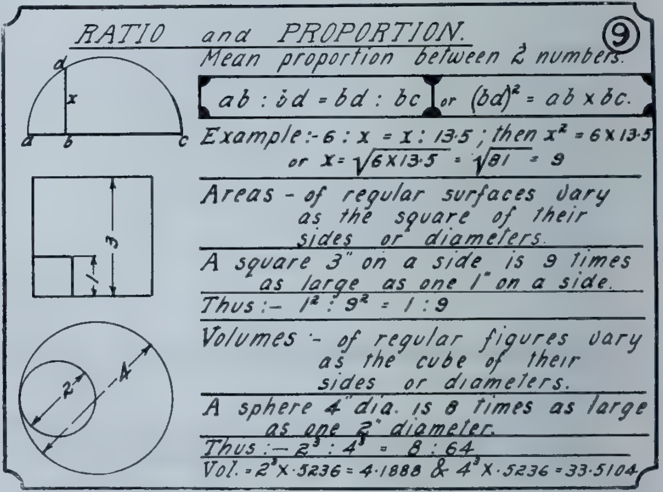
Then by using the 12 in. diameter as a driven pulley in place of the 14 in., we get the required result.

The areas of regular plane surfaces vary as the square of their sides or diameters. (See Chart 9).

A piece of steel 1 in. round, and 4 feet long weighs $10\frac{1}{2}$ lbs.; what is the weight of a bar of 2 in. round and 4 feet long?

$$1^2 : 2^2 = 10\tfrac{1}{2} : X \text{ or } X = \frac{2^2 \times 10\frac{1}{2}}{1^2} = \frac{2 \times 2 \times 10.5}{1 \times 1} = 42 \text{ lbs.}$$

To find the mean proportion between two numbers. (See Chart 9).



RATIO and PROPORTION. ⑨

Mean proportion between 2 numbers.

$ab : bd = bd : bc$ or $(bd)^2 = ab \times bc$.

Example:— $6 : x = x : 13.5$; then $x^2 = 6 \times 13.5$ or $x = \sqrt{6 \times 13.5} = \sqrt{81} = 9$

Areas — of regular surfaces vary as the square of their sides or diameters.

A square 3" on a side is 9 times as large as one 1" on a side.

Thus :— $1^2 : 9^2 = 1 : 9$

Volumes :— of regular figures vary as the cube of their sides or diameters.

A sphere 4" dia. is 8 times as large as one 2" diameter.

Thus :— $2^3 : 4^3 = 8 : 64$

Vol. $= 2^3 \times .5236 = 4.1888$ & $4^3 \times .5236 = 33.5104$

ARITHMETIC CHART 9.

The lesser is to the mean as the mean is to the greater of the two numbers.

What is the mean proportion between 9 and 16?

$$9 : X = X : 16 \text{ or } X \times X = X^2 = 9 \times 16 = 144$$

$$\text{then } X = \sqrt{144} = 12,$$

therefore

$$9 : 12 = 12 : 16.$$

Put Your Factory Equipment Needs Up to

GOODYEAR
TORONTO

Goodyear factory equipment has established a new efficiency standard in large and small manufacturing concerns throughout the Dominion.

Where "price" used to be the basis of purchase in these places, it is now *SERVICE.*

Belting now is bought on *service rendered* and *operating economy effected.* So is Hose. So are Packing and Valves. Manufacturers are buying Goodyear equipment because they know that they can get the very article for the very need—based on an actual investigation and study of the very requirement.

And in buying factory equipment this Goodyear *efficiency service* is yours without extra charge.

Belting

Transmission Belts that deliver all the power without undue strain on the pulleys and "coal pile." Each belt made to meet the very purpose for which it is designed. Each made for "pulling" power—without unnecessary bulk and weight.

"Leg" and "Bucket" Conveyor Belts. For carrying heaviest loads—coal, gravel, ore, grain, etc. Each made with the exact surface for the exact purpose. Carry the load with least wear and tear. Day in and day out utility insures real economy.

Special Brick Conveyor Belt—with oil-resisting stock face. Unaffected by oil that is shed by machine.

Tell Goodyear your belt needs. Learn beforehand of just the belt, *and why.* Then, no after regrets—no after expense.

Hose

Steam Hose, Air Drill Hose, Agricultural Hose, Hose for gas, acids, and hot and cold liquids. Each made with the special inner lining for its particular purpose. Hence, longer life—*greater service.*

Let Goodyear tell you of just the hose you need. Perhaps you have not thought much about it before. But it's a vital matter just the same, if you value time and money saving. Goodyear has already solved just such hose problems as yours.

Packing and Valves

Poor packing may serve today—and tomorrow. But it soon gives out. That means lost time—lost motion—expense.

Goodyear Packing gives you a tight joint whether the pressure is air, hot or cold water, or superheated steam. Will not blow out. Unaffected by expansion or contraction. Won't flow under intense heat or pressure.

Goodyear Valves are made for all purposes—from cold water to acids—low pressure and high pressure, air and steam. We will tell you the "why" of just the Goodyear packing and valves for your every purpose.

Use This Free Service Asking questions about your belting, hose, packing and valve needs, costs you nothing—involves no obligation. The Goodyear Efficiency Bureau will be glad to confer with you at any time. Write today.

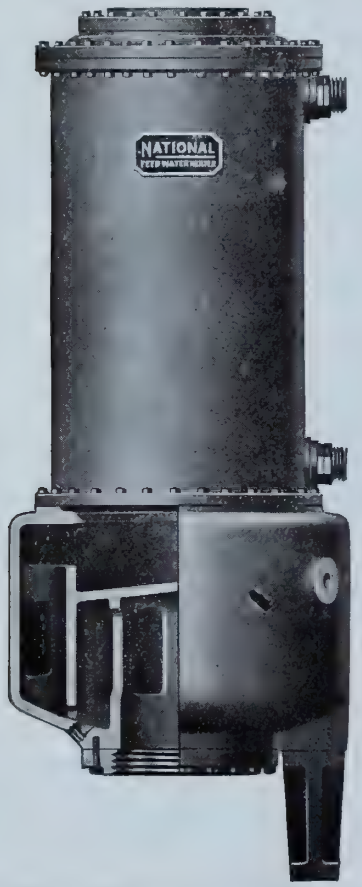
PROGRESS IN NEW EQUIPMENT

There is here provided in compact form a monthly compendium of the power plant manufacturers' achievements.

FEED WATER HEATER AND OIL SEPARATOR.

ONE of the recognized advantages of the closed feed water heater is the fact that the feed water is kept entirely free from the exhaust steam, which may contain considerable oil. This type of heater prevents oil getting into the boiler, even if no oil separator is used. When installed, the condensed steam continually leaves the heater through the drip pipe, which should always be left open.



NATIONAL FEED WATER HEATER AND OIL SEPARATOR.

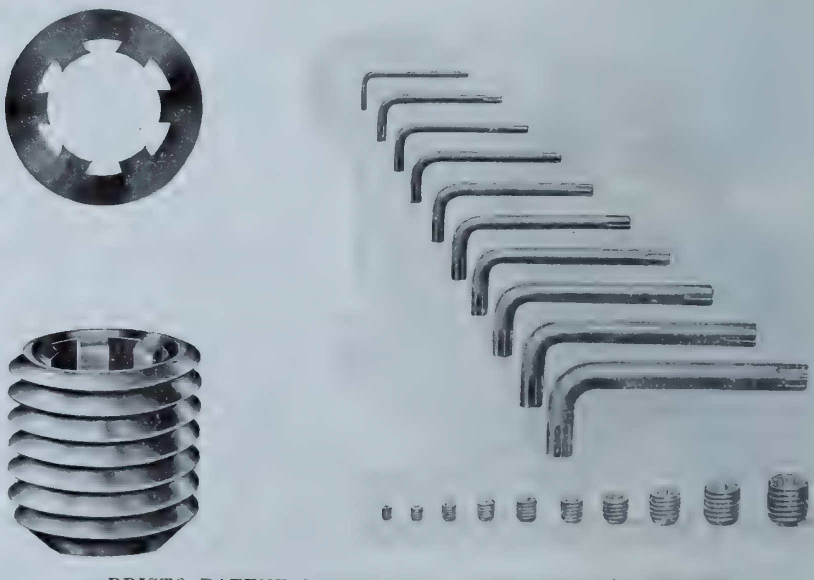
In some installations this condensed steam can be used to advantage in ice making, for washing, or by returning it to the boiler together with drips from a heating system or other apparatus; but the oil must be got rid of, and it is usually easier to take it out of the exhaust steam than to filter it from the condensation.

To facilitate installation, the National Pipe Bending Co. have made a special closed heater, with a separator forming part of it, instead of being detached. The separator is placed at the bottom of the heater, as shown in the accompanying illustration, so that the exhaust steam will impinge upon the baffles and by change of direction and passing through the ports shown, will be freed from particles of oil without adding to the back pressure on the engine. This is accomplished by a very careful design and a slight modification of the company's regular horizontal oil separator, which is distinguished chiefly by the individual baffles and arrangement of ports, having an area of 1½ times greater than that of the inlet pipe.

NEW PATENTED SAFETY SET-SCREWS.

THE Bristol Company, Waterbury, Conn., has recently put on the market a new and improved line of "BRISTO" Patented Safety Set-screws as shown in the accompanying illustration. These are manufactured under the Goodwin patent of October 14, 1913, and the patented design is shown in the cross section, from which it may be seen that there are six dove-tailed slots inside the hollow head of the set-screws, and six corresponding flutes on the outside of the special wrenches used with these. The dovetailed design is such that when the set-screws are set up hard with the special wrench, the latter gives the screw a true rotary motion without the usual tendency to expand and crack the hollow head. The angles of the surfaces of the slots are such that there is just a tendency for the wrench to contract or compress the head of the screw. The screws are manufactured in a great variety of sizes, a few of which are shown. A special treatment process is used which makes the screws glass hard on the outside and extremely tough on the inside, and samples have been found in actual test to be 100 per cent. stronger than the old hexagon style set-screws.

The "Safety First" movement has progressed so far that great attention is now being given to changing the design of machinery to protect human life and the elimination of the old style set-screws with projecting heads is one of the things on which safety engineers and insurance inspectors insist. At the First International Exposition of Safety and Sanitation recently held in New York City, a silver medal was awarded the Bristol Co. for its exhibit of safety set-screws.



BRISTO PATENT SAFETY SET SCREWS AND WRENCHES.

Are your Boilers Safe?

Many serious boiler explosions have occurred shortly after an inspector had reported them in good condition. A superficial inspection is worse than none. It is the duty of every steam plant manager to know the real condition of his boilers.

Scale is responsible for more boiler accidents than all other causes combined, and when its presence is discovered, don't try experiments with patent compound nostrums which require months to learn results, but put a good mechanical cleaner on the job that will show immediate results.

A LIBERTY TUBE CLEANER

will remove all the scale in record time, and at a low cost for upkeep. The hard proposition on which other makes of cleaners have fallen down are what we are looking for.

"TWINS" EXCITE ADMIRATION

Because They Earn It

Think of a TWIN when you hear the word STRAINER

The installation of a Twin Strainer on your water supply line eliminates troubles, worry, waste of time and expense—because

It has two straining baskets—that may be cleaned alternately, thus permitting continuous operation.

It has but two valves—they are of the gate type and are always tight.

It gives a direct flow with minimum friction loss, insuring easy operation with no waste of energy.

In fact, a Twin Strainer is an insurance policy in active service.

Designed to protect and built to last.

Write for our bulletin.

Catalogues

Pumps.—The Gray Mfg. & Machine Co., Toronto, Ont., have sent us a copy of a new bulletin No. 12, which describes the steam and power pumps which they make. A full line is dealt with, each type being illustrated together with a brief but comprehensive description.

Air Compressors.—The Canadian Ingersoll-Rand Co., Ltd., Montreal, Que., have sent us a leaflet descriptive of the class "N" compressors which they make. The advantages claimed for this compressor are set forth in a comprehensive manner accompanied by illustrations of other types.

J-M Pipe and Boiler Insulation, catalogue No. 100, deals with the asbestos and magnesia products of the Canadian H. W. Johns-Manville Co., Toronto. A complete line of pipe covering and boiler insulation is illustrated and described. Tables are included giving thickness, weights and prices of sectional pipe coverings, while prices for other products are also given. The catalogue has an attractive cover and a complete index.

Direct Current Generators, small, belted type are described fully in bulletin No. A4188, issued by the Canadian General Electric Co., Ltd., Toronto. The bulletin contains a detailed description of the C.V.C. type of generator, with illustrations showing all the parts disassembled and the belt-tightener attachment. Diagrams are included accompanied by a table giving the principal dimensions and other data for each size of generator.

The C. C. Self-Cleaning Strainer is described fully in a booklet entitled "Protecting the Hearts of Industries," published by the Crane Valve Company, Bridgeport, Conn. The advantages claimed for this strainer are set forth and a sectional view shows clearly the method of application. A table is included giving the prices for the various sizes and another table accompanied by diagrams gives the principal dimensions for each size.

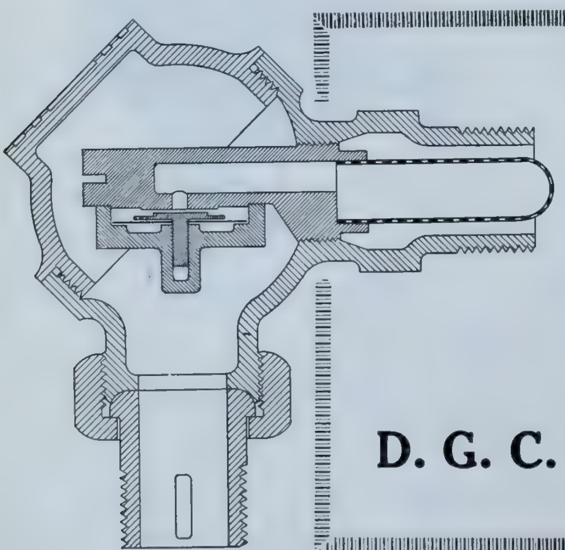
"Grundy" Coupling made by the Canadian Bond Hanger & Coupling Co., Alexandria, Ont., is the subject of leaflet "D," being distributed by the above company. A complete description, with illustrations, is given of the coupling which is of the flexible insulated type for motor drives of all kinds. A table is included giving the prinicipal dimensions of each size and there is also included a useful telegraph code for use when ordering couplings. Copies may be obtained from the Toronto office, 82 Adelaide street, east.

The Grinnell Automatic Sprinkler bulletin for April has come to hand. This bulletin, which is published quarterly by the General Fire Extinguisher Co., New York and Providence, contains photographs of prominent buildings, showing the damage done by fires, with a brief commentary on each. Reference is made to an equipment of "Grinnell" automatic sprinklers on the S.S. "Imperator" and "Vaterland," accompanied by illustrations. A record of fires in buildings equipped with the "Grinnell" sprinkler is given with the loss in each case recorded.

Avery Automatic Scales are described fully in catalogue No. 117, recently issued by the Avery Scale Co., North Milwaukee, Wis. The scales dealt with in this catalogue are principally designed for weighing coal, although some of those described are intended for handling other materials. The principal features embodied in the "Avery" automatic scales are dealt with in a comprehensive manner, accompanied by illustrations of the scales and also of several installations in boiler rooms. The "Avery" patent totalizer is also described and illustrated. On the concluding page is a diagram of an automatic coal scale with a table giving the approximate dimensions for the various sizes. Copies of the catalogue may be obtained from the Canadian agents, Canadian Allis-Chalmers Ltd., Toronto, Ont.

Book Reviews

"Conservation of Coal in Canada" is the title of a report published by the Commission of Conservation appointed by the Dominion Government, and compiled by W. J. Dick, mining engineer of the commission. One striking feature indicated by the report is the dependence of Canada upon the United States for its supply of anthracite coal. This is clearly indicated by means of a map, various sections being colored, to show the origin of coal used in the different areas. It is within the range of possibility that the United States may in the near future prohibit the export of anthracite. Such a situation makes it clear that Canada should husband her coal resources and prevent waste as far as possible. With this in view the report suggests changes in coal mine leases. In addition, it is urged that the government should carry out investigation as to the suitability of low grade coals for use in gas producers and in the manufacture of briquettes for domestic use. Several pages are devoted to descriptions of briquette plants and coke ovens. The greater part of the report, some 163 pages, contains a description of the various mines in the provinces where coal is found, covering such matters as quality, method of mining, equipment, ventilation, etc. The report contains several excellent photographs, tables giving thicknesses of coal seams, diagrams of mine interiors and two folding maps.



D. G. C. Valves

guarantee a perfectly regulated heating system with economy in steam, and no back pressure on the engines.

Unlike all other valves, it has no springs, no floats, no counterweights, no thermostatic plugs, no regulating screws, and NEVER REQUIRES ADJUSTMENT.

It is fool-proof, and cannot get out of order.

If you want to get EVERY CENT'S WORTH OF STEAM let us give you full particulars on the Valve that will do it for you—the D. G. C.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS

TO THE STATIONARY ENGINEER WHO IS NOT A MEMBER OF THE C. A. S. E.

Have you ever seriously considered the necessity of mingling freely with your fellow-men whose life's occupation is the same as your own? If you have not, I would like to place before you the advantages which accrue to all thus associated.

We preach the doctrine of elevation of the Engineers through the medium of education.

By joining one of the subordinate associations of the C.A.S.E. you can gain knowledge of the character which is deemed so essential by successful practitioners of all the useful professions.

In all fairness I would ask you if an organization devoted to the calling at which you earn your daily bread is not entitled to special consideration from you?

For further particulars write

A. KASTELLA

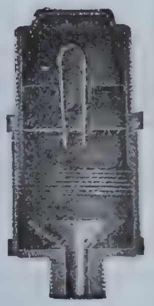
MANZEL BROTHERS COMPANY, BUFFALO, N.Y.

WHY USE OIL

When GREASE Gives More Uniform Lubrication, Is Better and Much Cheaper?



This Grease Cup will pay for itself many times over with the money it saves in lubricants.

You know that Oil cannot be properly controlled—much of it is lost through dripping.

Grease when used in this Grease Cup is under perfect control until the last drop is used.

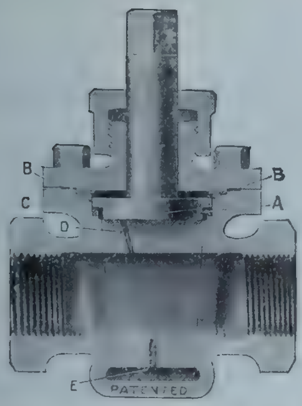
The efficiency of this Grease Cup cannot be affected by centrifugal force when used on loose pulleys.

REMEMBER we guarantee it to save 50% over any other system.

Give it a trial and be convinced.

Write for particulars.

Peterborough Machine and Lubricator Co., Limited
Peterborough, Ontario



A Guaranteed Valve

For Every Purpose

Engineers will tell you that Homestead Valves are the best for all Water, Air or Steam lines. This they have learned by experience

Simple in construction, easy to operate, and the only valve which will successfully stand up under the heaviest duty service.

Made in Straightway, Threeway and Fourway patterns. Special valves for special purposes.

Send for Catalog "R."

Homestead Valve Mfg. Co.
Works: Homestead, Pa. Pittsburgh, Pa.

There Are Over 800 Otis Heaters in Buffalo Alone

EXHAUST INLET EXHAUST OUTLET
OTIS TUBULAR HEATER STEWART HEATER CO. BUFFALO N.Y.
COOL SETTLING CHAMBER

Throughout the various states, thousands upon thousands of horse-power are in use.

Why this popularity?

Because Otis Heaters occupy a place in the engineering world that is second to none.

It is the only pressure heater made that contains an effective oil separator and cool settling chamber.

The exhaust is the heating agent, and 212° is the ordinary, not the spasmodic, temperature of the water.

The Otis has unusually large capacity and heating surface, and is tested under 200 lbs. hydrostatic pressure.

There's a "rock-ribbed" guarantee that covers every function and part of the Otis Heater.

Try it for 30 days at our expense. You have nothing to lose, and much to gain.

Catalog on request.

Stewart Heater Company
189 Norfolk Ave., Buffalo, N.Y.

Don't Guess Any More!

With this instrument you can accurately count the revolutions of any revolving part.

For speed tests on engines, generators, turbines, or any machinery, nothing is so reliable and accurate as the

Starrett Speed Indicator

It indicates the highest speed without heating. Small and convenient. Three styles—$1.00, $1.50, and $3.00.

Send for free catalog No. 20 CD *and see what style you need.*

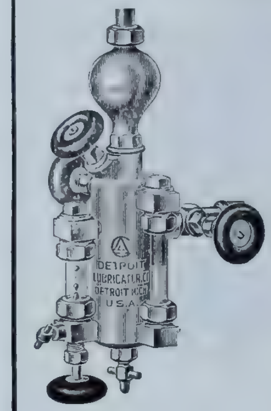
Athol, Mass.

Detroit Lubricators for every purpose

The Detroit line includes lubricators for service with every type of steam or gas engine, air compressor or machinery of any kind. One of these lubricators will enable you to eliminate every element of chance or uncertainty from the lubrication of your machine.



Every Detroit Lubricator is the product of scientific study of the conditions under which it operates and embodies every requisite for efficient, dependable, economical lubrication.

The big Detroit catalog tells about all the different kinds of Detroit Lubricators and gives valuable information on the lubrication of all kinds of machinery.

Write to-day for catalog G-58.

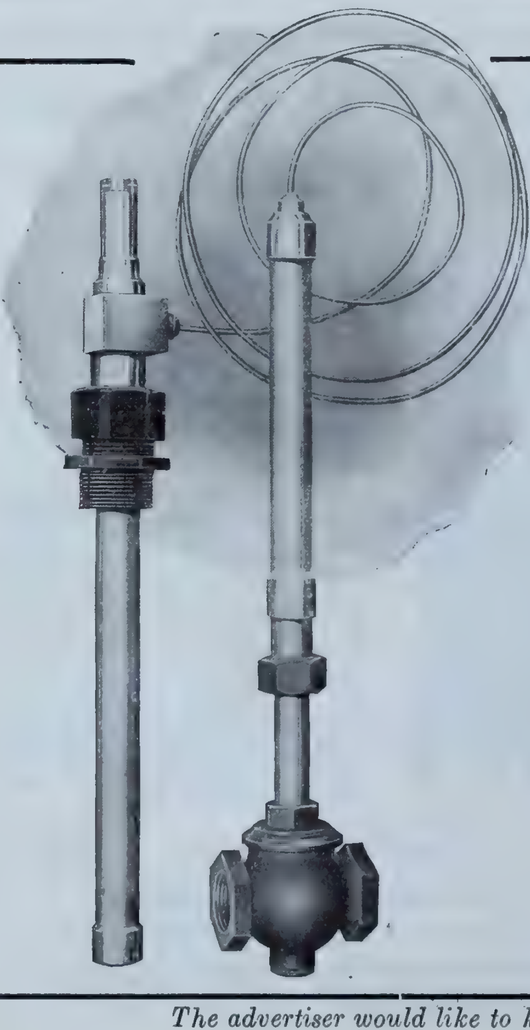
WALKERVILLE, ONT.



Slight Temperature Variations May Mean Heavy Losses

in many delicate manufacturing processes. If such a process is involved in the making of your product, you realize how vitally important it is that your thermostatic regulator should be absolutely accurate.

"SARCO"

Water Temperature Regulators

Are Good Insurance

against such losses.

Sarco Regulators depend for their action upon a principle that is absolutely positive and unchanging. The action of the thermostatic element depends on the expansion of a sensitive liquid hermetically sealed within a chamber. Into this chamber is inserted a flexible corrugated tube connected with valve-operating mechanism controlling steam or hot water inlet, according to the temperature in the tank or room.

No leaky air-valves, perishable rubber or leather diaphragms, or variable metal disc diaphragms are used in the Sarco. Sarco-Regulators are exceedingly simple and cannot get out of order.

Let us send you a bulletin with diagrams and descriptions of this instrument. Write for it.

We also sell "Sarco" Steam Traps, "Sarco" Smoke Recorders and "Sarco" Automatic Combustion Recorders. Bulletins sent on request.

A. R. ROBERTS
Winnipeg, Man.

"DROP AROUND—

and see us, next Sunday, Bill," says a fellow engineer. And you are on the point of accepting, because you would like very much to go; when you remember—and you shake your head: "Sorry, old man, I can't, I've got to open up the boilers; there's any amount of scale in them; I can't get any steam! And I guess it will take me all Sunday to fix them."

A wasted Sunday and a lot of hard work! All of which could have been prevented by dosing your feed-water with WALKER'S ELECTRIC BOILER COMPOUND.

Think this next time—and meanwhile get our catalogue of Steam Users' Supplies.

The Electric Boiler Compound

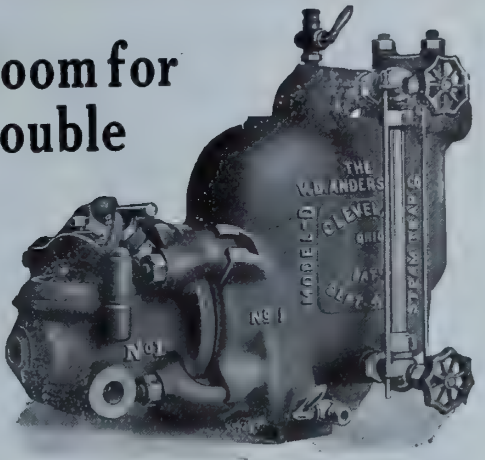
No Room for Trouble



in your heating system if you use the

Anderson
Model "D" Steam Trap

IT IS A CONTINUOUS, RELIABLE AND STEADY DRAINER, which disposes of the condensation as fast as it accumulates, without permitting live steam to escape.

The Valve and Valve Seat can easily be changed from high to low pressure, or vice versa, in five minutes, without disturbing or unscrewing a single joint or pipe connection. We supply Valves and Valve Seats for any pressure.

THE CUT BELOW SHOWS THE COMPLETE WORKING MECHANISM OF A MODEL "D" TRAP, consisting of Hanger, Float Lever, Counter Weight, and Valve Connection assembled ready to fit into its place on the head. These assembled parts are very accurately built, and fitted up with just the right amount of play to allow the expansion and insure free-working.

There's a lot more we would like to tell you.

Write for descriptive booklet.

Spending Sundays in a Boiler?

Are you one of the many engineers who are forced to work on Sunday in order to keep your boilers free from scale? There was a time when the old method of "digging-out" scale was a necessity. Times have changed. Scale can now be removed and prevented by treating the feed water with

McColl's Special Boiler Compounds

or Feed Water Treatment

A small quantity of this treatment used daily in your feed water will keep your boilers as clean as a pin and save you many hours of dirty, unpleasant work. **Let us give you full particulars about this Boiler Compound. It's like our oils, best by test.**

We treat each case thoroughly and individually, and guarantee good results.

McCOLL BROS. & COMPANY
WINNIPEG
MONTREAL TORONTO
and VANCOUVER

Electric Boiler Scale Picking Machine, Devoorde Patent

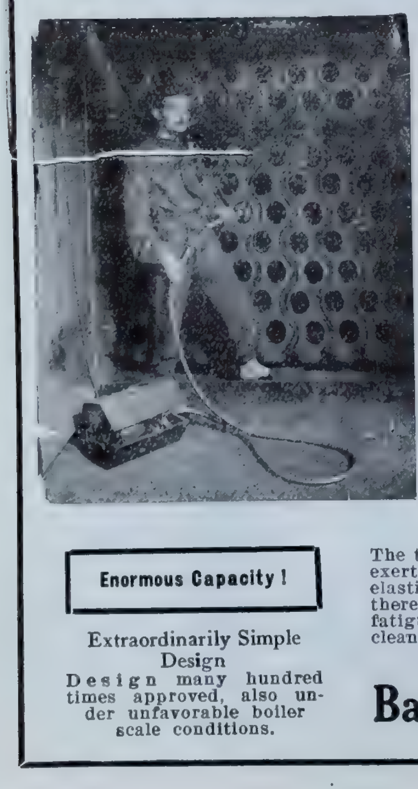
Type F: For Fire-tube Boilers, etc., also for Picking the Grates Crusts, etc. For Cleaning Ship's Skins and for Sharpening Millstones.

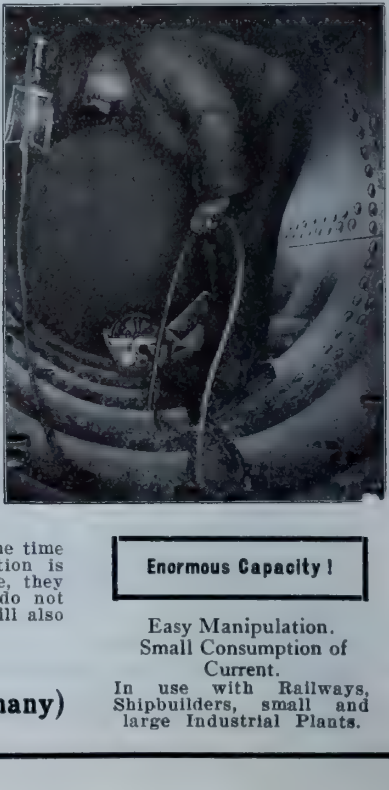
Type R: For Cleaning the Tubes of Watertube Boilers, Steep-tube Boilers, Economizers, Vacuum Apparatus, etc. (also suited for narrow and slightly curved tubes).

Type C: Combined installation.

Splendid Testimonials at Disposal! Great Advantages!

Approved where other Types Failed





Enormous Capacity!

Extraordinarily Simple Design
Design many hundred times approved, also under unfavorable boiler scale conditions.

OPERATION:

The three Pickers strike about 7200 times a minute and at the same time exert a tearing effect. The Pickers are pivoted and their action is elastically damped in a natural manner by the centrifugal force, they therefore operate free of all shocks, require very little power, do not fatigue, do not wear the edges of the pickers, **do not burr** and will also clean inaccessible parts.

Beware of inferior imitations.

Bader & Halbig, Halle a. Salle (Germany)

Enormous Capacity!

Easy Manipulation.
Small Consumption of Current.
In use with Railways, Shipbuilders, small and large Industrial Plants.

BAWDEN

Five Questions and the Answer

No. 1. Are you getting the greatest amount of efficiency out of the fuel you are burning?

No. 2. Are the interior surfaces of your Boilers coated with scale?

No. 3. Are the interior surfaces being corroded or pitted?

No. 4. Does your Engineer experience any trouble in the form of foaming or priming?

No. 5. Are your Boilers leaking around the seams and joints?

The Treatment of Boiler Feed Waters

Specified causes must be treated **specifically.** No "cure-all" will act as the proper re-agent to prevent the formation of deleterious substances under any and all conditions.

DEARBORN WATER-TREATING PREPARATIONS are scientifically prepared to meet the requirements of the mineral ingredients and other objectionable constituents of the waters used in **your** boilers. The services of the Dearborn Laboratories are offered free of charge to all power plant operators who experience difficulties due to unsatisfactory boiler-feed supplies.

Our Booklet Explains All

Write for a copy to-day. It gets right down to the root of feed water troubles, and will prove of value to any manufacturer or engineer.

Pratt & Cady Valves

with Renewable Bronze Seat Rings

Those who are looking for a valve of the highest grade, one which they can rely upon to help in their "Safety First" campaign, will do well to choose the P. & C. line of gate valves, made in Brass and Iron from 1¼″ up; they all have the same

Retaining Ring Construction

The seat rings are independent rings of bronze, or any special metal or material best adapted for the service in which the valve is to be used. These seats can be renewed by removing the retaining rings with a suitable wrench made for the purpose, or other appropriate tool. The gate is a double-faced, wedge-shaped casting, with side grooves by means of which it slides on guides in the valve body.

Great pains are taken in the machining of all parts of these gate valves. Gauges are used on each part to insure their accuracy and interchangeability. The guides in the bodies are of equal thickness, and the wedges can be taken out of the valve and replaced with the opposite faces in contact, and will give an accurate fit. The importance of this in making repairs is obvious. These valves being double-seated can be used with the pressure applied at either end.

For Superheat and High Pressure, Wet Steam and Oil, use Durabla Packing.

Those who wish to sell or buy a business, obtain competent help, connect with satisfactory positions or secure aid in starting new enterprises, should not fail to use the Want Ad. Page of The Power House.

Do you want to sell or buy a second hand engine or any other equipment? Let The Power House pick out a seller or buyer for you.

There is always some one looking for just such proposition as you have to offer.

RATES (payable in advance):—2c. per word first insertion, 1c. per word subsequent insertion, 5c. additional each insertion when Box Number is required. Each figure counts as one work.

FOR SALE

FOR SALE—CANADIAN RAND UPRIGHT Air Compressor—5½ x 8" Plunger—36 x 6½" Fly Wheel. Nearly new. Canadian Rand, Horizontal Class "E" Air Compressor, 10 x 14. Nearly new.

Quantity of Special Hangers—Bearings and Collars—mostly new.

Details of the foregoing upon application to Taylor-Forbes Company, Ltd., Guelph

FOR SALE
POWER EQUIPMENT

- 2 Double Duplex, high pressure Water Pumps.
- 5 60-in. x 16-ft. Return Tubular Boilers, allowed 125 lbs. steam.
- 2 125 h.p. Water Wheels.
- 1 Upright Engine for sawdust conveyor.
- 1 10 h.p. Engine.
- 1 Mitts & Merrell Hog.
- 1 Wood Machine for 22-in. wood.
- 1 Wood Machine for 16-in. wood.
- 1 Edger for ripping dry lumber, installed.
- 1 Edger for ripping dry lumber, not installed.
- 1 30 h.p. Generator, 250 volt.
- 1 30 light arc generator.

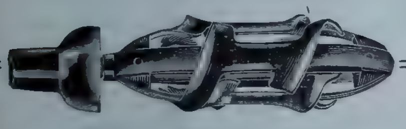
There is also a large quantity of shafting, pulleys, hangers, belting, tram cars and rails and turn-tables, particulars of which may be had on application.

Also, contents of machine shop, containing Planer, Drill, Lathe and Machinery, with tools necessary for repair work.

All of the above open for inspection at Parry Sound.

Also Complete Saw-mill Equipment.

The
Parry Sound Lumber Co., Ltd.
26 Ernest Ave Toronto, Canada



Model A, $1.10 per inch.

THOMAS' IDEAL FLUE CLEANER

Patent 1911

Has cutting edges of chisel shearing shape on both ends, which shave flue as clean as day it was made. Adjustable to wear—easily sharpened—strongly built. Made to do the work.

The IDEAL is the most perfect cleaner on the market to-day.

Sold on guarantee from your dealer or direct from manufacturer.

Manufactured by
S. I. THOMAS, 6 Afton Ave.
Toronto, Can.

Model B, $1.00 per inch.

Boiler Preservative

acts on the iron—not on the water. It is a boiler treatment in a class by itself.

Water treatments are only partially successful, because the scale-forming sediment in water changes with seasons, climates and localities.

"**MAGIC**" removes scale and oil first, and then prevents scale forming. It stops pitting, corrosion and minor leaks.

"**MAGIC**" saves the boiler and much labor.

A trial will convince you—write us.

THE BAR-KEEPER'S FRIEND

Best known Metal Polish Guaranteed forever. Largest sale in the World.

One of the most successful retailers of late years says: "When a firm advertises in trade papers it is getting into good company. As I pick up one of a dozen of these periodicals here in my office, and glance through it, I find that the best people, the successful firms, are represented in such a way as to reflect their importance in the trade."

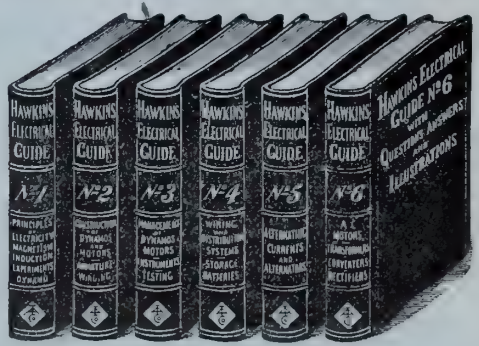
HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books
Price per Volume $1

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.



HAWKINS ELECTRICAL GUIDE No. 1 PRINCIPLES OF ELECTRICITY MAGNETISM INDUCTION EXPERIMENTS DYNAMO
HAWKINS ELECTRICAL GUIDE No. 2 CONSTRUCTION OF DYNAMOS AND MOTORS ARMATURE WINDING
HAWKINS ELECTRICAL GUIDE No. 3 MANAGEMENT OF DYNAMOS MOTORS INSTRUMENTS TESTING
HAWKINS ELECTRICAL GUIDE No. 4 WIRING AND DISTRIBUTION SYSTEMS STORAGE BATTERIES
HAWKINS ELECTRICAL GUIDE No. 5 ALTERNATING CURRENTS AND ALTERNATORS
HAWKINS ELECTRICAL GUIDE No. 6 A.C. MOTORS TRANSFORMERS CONVERTERS RECTIFIERS
HAWKINS ELECTRICAL GUIDE No. 6 WITH QUESTIONS ANSWERS AND ILLUSTRATIONS

"THAT'S JUST WHAT I NEED"

Read over the titles shown on the back of each volume, and note the scope of each book. They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED.

FREE EXAMINATION OFFER

THEO. AUDEL & CO., 72 5th Ave., NEW YORK

Please submit me for examination HAWKINS ELECTRICAL GUIDES (Price $1 each.)

Ship at once, prepaid the 6 numbers; if satisfactory I agree to send you $1 within seven days and to further mail you $1 each month until paid.

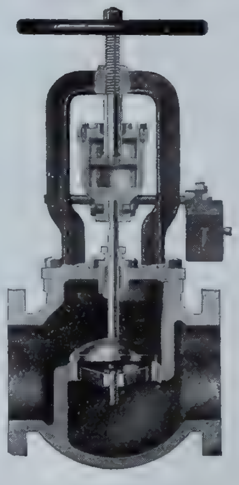
Consider Well These Features of the Davis Class C Before You Decide Upon the Type of Stop and Check Valve that You Are Going to Use.

Service—It will prevent a reverse flow of steam in case of an internal rupture to any one of the boilers in the battery. It isolates any boiler that is not up to the average header pressure.

Dependability — It will not stick. It has an outside oil dash pot. Scale formation or expansion of the parts cannot interfere with its operation.

Indicator — The counterweight lever moves in unison with the disc. The action of the valve is always visible.



Globe and Angle Patterns

Noiseless—The oil dash pot is effective no matter how small the movement of the disc may be. It cannot pound.

Test—The condition of the internal parts can be easily determined at any time. The counter-weight lever affords means of testing by hand.

Maintenance—The disc and seat may be reground and both are renewable. The stem is packed at the factory with long-lived metallic packing.

Westinghouse Leblanc Condenser and Air Pump

The success of condensing apparatus depends upon the complete and immediate removal of air from the condenser vessel.—In this respect the Leblanc Air Pump has successfully defied competition.

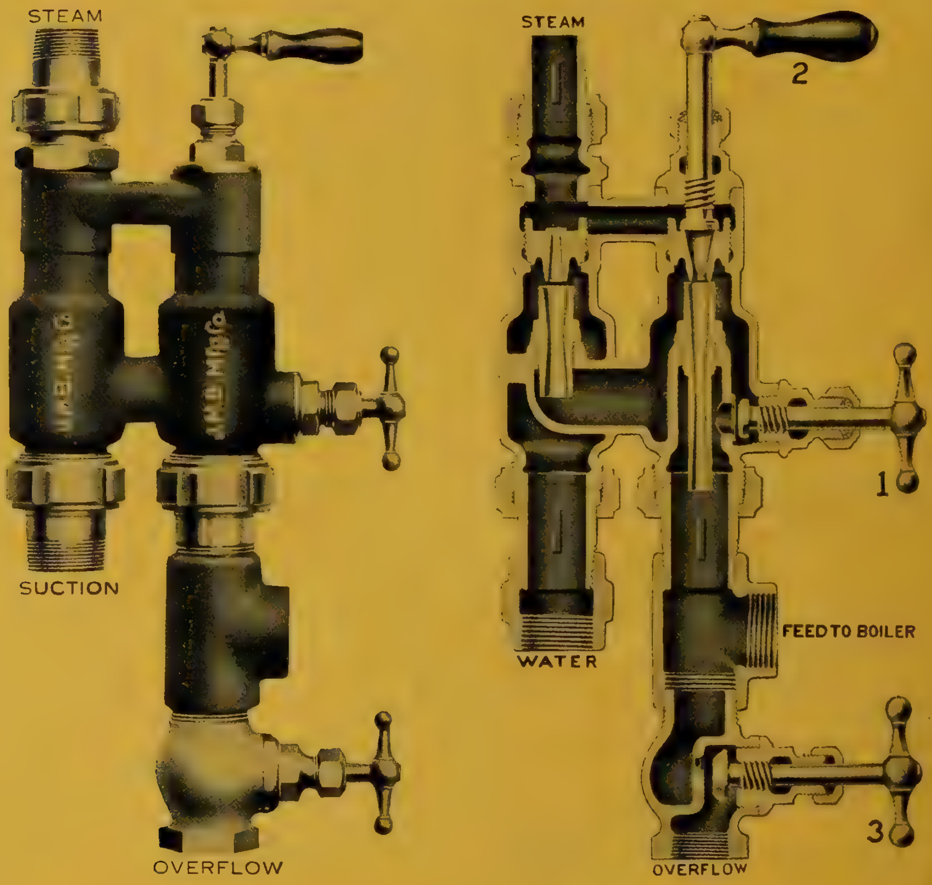
The Genuine

Hancock Inspirator

for Stationary Boilers

WITHOUT A RIVAL FOR OVER THIRTY YEARS



NEARLY HALF A MILLION NOW IN USE

The Boiler Feeder Without an Equal

THE HANCOCK Inspirator, as illustrated, is a double tube (lifting and forcing) injector of a peculiarly simple and efficient type. For general all-round service it has no equal. It works with high or low steam pressure on all lifts up to twenty-five feet, or when taking water under a head, with hot or cold feed water in either case. For all steam pressures and under all conditions its operation is the same, and it requires no adjustment for varying steam pressures. It will feed water at any temperature up to 150 degrees Fah., and will operate at any steam pressure from 15 to 240 lbs. gauge.

The oldest, the best tried, and most generally satisfactory injector ever built.

Manufactured and Sold in Canada Only by

The James Morrison Brass Manufacturing Company, Limited
93-97 Adelaide Street West, TORONTO, CANADA

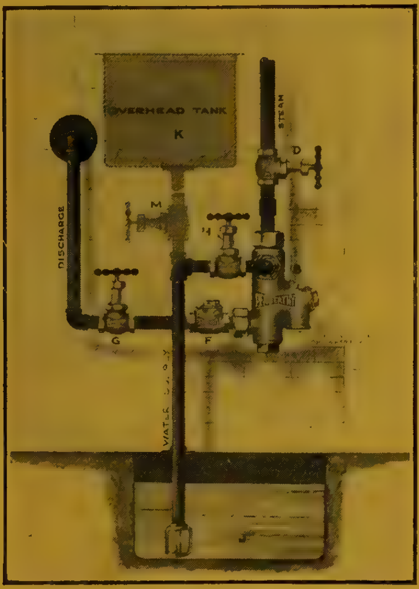
"The All Quality Line" TRADE PENBERTHY MARK *"The All Quality Line"*

Automatic Injectors and Regrinding Valves
Make the Best Combination



Penberthy Automatic Injectors will be found most efficient when connected up with Penberthy Globe and Check Valves.

"The Valves That Give the Service"

Every engineer and power plant owner who wishes to run his plant to its full capacity, efficiently and economically, is strongly urged to equip same with Penberthy all quality valves.

Approved by Public Works Departments of Ontario and Western Provinces for steam pressures as high as 200 lbs. Write for booklet "Something Better in Valves" to-day.

Penberthy Injector Co., Limited **Windsor, Ont.**

Waterous Boilers

Mean Economy In The Power Plant

IT is no trick to get the full steam value from the fuel you burn if you use Waterous Return Tubular Boilers installed the Waterous way.

Combined with the natural advantages possessed in general by this type of Boiler—economy in fuel consumption, large steaming capacity, ability to use hard and dirty water, and comparative low cost—we can furnish you with a boiler setting that is designed and dimensioned to best handle the fuels you use.

Whether you are burning coal, wood, sawdust or shavings, or combinations of these, we will install your boiler to give you the highest efficiency and the most perfect combustion possible with your particular fuel.

We build and carry in stock Return Tubular Boilers up to 72″ x 18′. If we cannot supply you at once from our yards we can turn out your order in quick time. Ask us for prices on the next boiler you buy.

"Frost King" Babbitt

Is especially designed for **STATIONARY Engines, Pumps, Rolling Mills, Saw Mills, Planing Mills,** and **Pulp Machinery.**

Over thirty-five years' experience in selecting and compounding of metals is behind it, and, we believe, there is no other make that can equal it in efficiency and practical economy.

Our "NICKEL GENUINE" Babbitt is especially adapted for babbitting dynamos and motors.

If your dealer cannot supply you, write us, and we will take pleasure in making you a shipment of a twenty-five pound box.

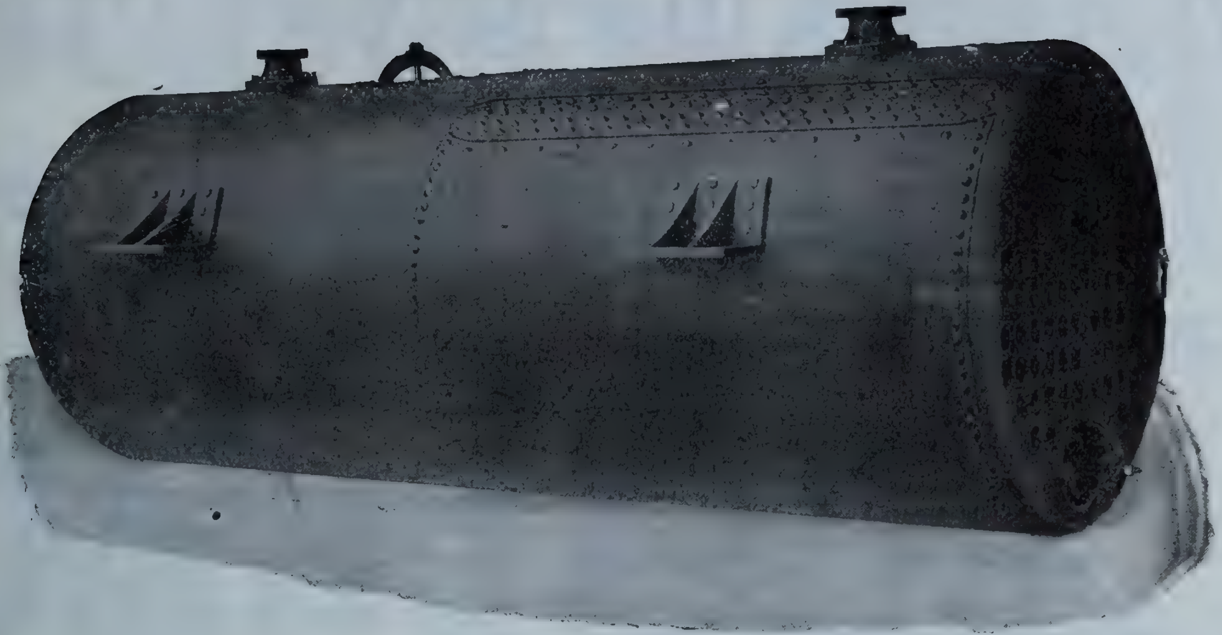
MADE IN CANADA

HORIZONTAL TUBULAR **VERTICAL TUBULAR** **HEATING BOILERS** **LOCOMOTIVE TYPES**



JENCKES BOILERS

Flange quality steel conforming to Manufacturers' Standard specifications, is used in shell and heads. The tubes are lap-welded steel of standard gauge and make; the rivets of special quality rivet steel, and the stays of steel, without welds.

Our facilities are modern and complete, our workmen have been trained in our own shops, and the construction of our Boilers is painstaking and thorough throughout.

Upon completion all boilers are tested to a hydrostatic pressure of at least one and a half times the required working pressure before leaving the works.

Helping you to become thoroughly familiar with the service of our boilers is a service that we render with great pleasure.

Write us to put you in touch with users, and to send our Catalogue.

but the

DART UNION

—NEVER

It always gives Efficient and Economical SERVICE

When connected it is really the strongest and safest part of the pipe line.

Both faces are of BRONZE, which you know will not rust or corrode, and being ball-shaped, permanently tight connections can be made easily and quickly, whether pipes are in or out of alignment.

Vibration, contraction or expansion have no effect on the efficiency and long life of the "Dart."

Every Dart Union bears the trade-mark as shown on illustration. We replace two for one, if a Dart is defective.

Sold by Jobbers from Coast to Coast

Manufactured by
Dart Union Co., Limited
Toronto

BRONZE TO BRONZE AT THE JOINT

Stop Blow-outs and Leaks in Pipe Lines by Using GOETZE No. 2 ELASTIC GASKETS

If you start right now to renew with No. 2 ELASTIC GASKETS, you can steadily reduce your renewals until you have brought them almost to the vanishing point.

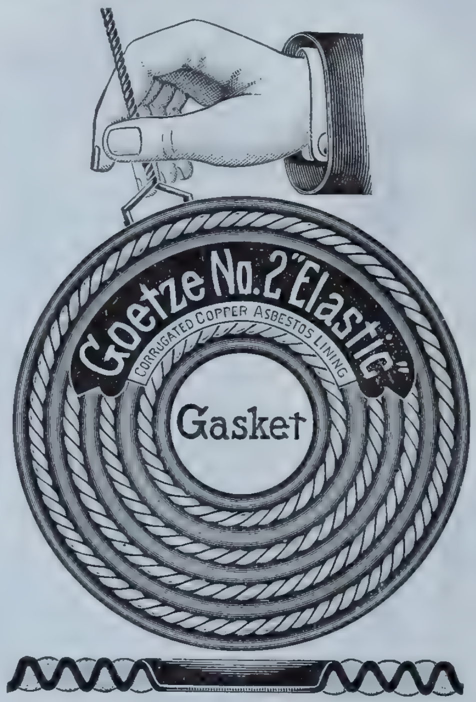
This is not a mere "claim"—it is backed up by a *guarantee*—in fact the strongest guarantee ever made by a gasket manufacturer.

Think what it means to re-gasket a joint so it will *keep tight for years,* instead of days or **weeks.** Think of the saving resulting in gasket costs, labor and shut-downs.

What No. 2 Elastic Gaskets Will Do

No. 2 Elastic Gaskets will make the most troublesome joint you have absolutely tight — and keep it so. They "stay put" and stay tight. Prevent leaks, blow outs and shut-downs. Will practically eliminate renewal expense for gaskets.

No. 2 Elastic Gaskets are for high pressure and super-heated steam lines, but owing to their indestructible nature, are equally adapted to *any and every condition* about a factory, mill or refinery.



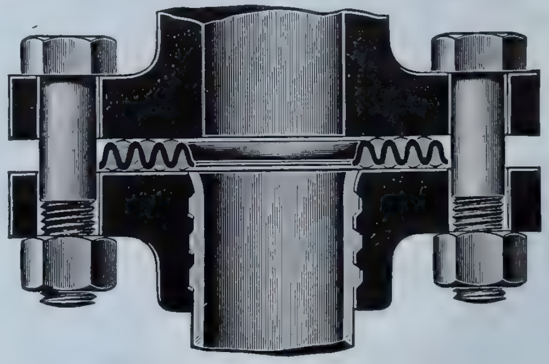
The No. 2 Elastic Guaranteed

Every No. 2 Elastic Gasket is Guaranteed for 5 Years' Continual Service in the Same Joint

There are no "ifs and ands" about this guarantee. It means just what it says. It applies to every No. 2 Gasket whether bought direct from us or through a dealer.

How No. 2 Elastic Gaskets are Made

These Gaskets are made of corrugated copper with asbestos lining No. 2. The corrugations allow for expansion and contraction of the pipes, while the asbestos, being forced into the pores of the metals in the flanged surface by the "squeeze" and the constant pressure of the corrugations beneath it, holds securely against the highest pressures.



Goetze Gaskets are carried in stock by

Don't Hit Him

Of course, it makes you "hot under the collar" to be considered "easy," and not able to see the difference between worthless imitations and "the real thing," but do not hit the fellow who tries to "work" you—simply show him the door, and stick tighter than ever to the only trouble-saving packing: the kind you know and trust.

DANIEL'S ROD PACKING

P. P. P.

FOR STEAM, AIR, WATER, AMMONIA

Did you ever stop to think why so many makers copy the form of P. P. P., and some of them the ideas and wording of our advertisements? Isn't the answer that the imitators admit the superiority of P. P. P.? Why accept "bad seconds" when you can get the GENUINE?

Again we say: P. P. P. will save 75% to 90% of the rod friction necessary to hold your engine steamtight. P. P. P. holds on rods that are worn, scored or out of line. P. P. P. makes rods as smooth as glass. P. P. P. saves trouble for the engineer and money for the "boss." P. P. P. backs up every statement we make. P. P. P. is successfully used by thousands of engineers to pack every type of engine, pump, expansion joint, ice machine, etc.

License Examination Book FREE

Remember P. P. P. is the ORIGINAL "sliding wedge" DIAGONAL rod packing. To see if you know which packings are **imitations** of P. P. P., we offer you a Book of Questions and Answers to License Examinations, if you return this coupon filled out and **the name of one or more packings that you consider IMITATIONS of P. P. P.**

Cling-Surface effects savings in more ways than you can imagine.

Savings from the use of Cling-Surface pop up from many sources: Where belt slip is stopped without tightening belts and its attendant useless increase of bearing pressures, coal is saved in quantities, year in and year out, that pays for the Cling-Surface and its application dozens of times over. Cling-Surface treatment more than doubles or trebles the life of belts that otherwise are run tight, for the pliability and softness which it imparts to both interior and exterior permit the belt to run slack with less slip than is present in a tight belt.

The truth of these statements is forcibly emphasized in the following remarks of Mr. Jerry Lynch, 196 East 205th St., New York, a self-styled "Cling-Surface Bug" who was put in charge of M. P. Davis' plant, Niagara Falls, Ont., where belts were once run extremely tight:

"They burned out many sets of main bearings on those compressors. After Cling-Surface came, I asked them to allow the belts to go on without taking up, which they did. We cut the oil bill from five gallons a day to five gallons a week, and once ran for over three months without stopping, and no trouble."

Mr. Lynch was there 25 months. During that time they needed *only one gallon* of Cling-Surface.

This is perhaps an exceptional case, and an extremely high oil-saving record. But it is important in helping to prove Cling-Surface treatment the logical solution for belt troubles.

Belts partially ruined because of wrong treatment or no treatment can still be reclaimed with Cling-Surface, which, applied correctly, nourishes all the good still in them and checks the deterioration. Ask anyone who is using Cling-Surface. Give Cling-Surface a trial or at least write for more information to-day.

We quote f.o.b. Toronto.

Educational Talks on Leather Belting.

Proper Selection of Belting

The remarkable improvement in the manufacture of leather belting, made necessary by the development of modern efficient machinery, is of little avail if the proper selection and application of belting are neglected.

The use of unsuitable belting invariably results in increased expense due to one or more of the following objectionable features: excessive or uneven stretching, slippage, undue friction in bearings, loss of power, frequent interruptions to machinery and consequent loss in production, to say nothing of the early destruction of the belting.

On the other hand, the adoption of belting constructed to meet each condition of service insures low cost of operation and maintenance, as well as the maximum production from machinery.

There is one best belt for every drive.

For Vertical Drives—Belts of as light weight as is consistent with sufficient tensile strength to transmit the required power.

For Quarter Turn Drives—Belts of special construction, those for quarter turn to left made different from belts to operate on quarter turn to right.

For High-Speed Work—Heavy single belts with special laps, or light double belts.

For Intermittent Loads—Heavy belts with high coefficient of friction.

For Exposure to Steam, Gas or Oils—G. & K. Spartan Belts made from leather specially tanned and curried and put together with a special cement.

For Exposure to Water or Moisture—G. & K. Neptune and Spartan Waterproof Belts put together with Waterproof Cement — the use of either brand depends entirely upon the construction of the drive.

From the foregoing, the absurdity of adopting one quality and weight of belting for all drives is apparent.

To meet different conditions of service we manufacture several brands of belting, each rigidly graded as to quality, weight and thickness.

Our Engineering experts will gladly assist you in analyzing any type of drive or in the selection of belts calculated to render the greatest service. Consult us freely.

This Mark On Belting

is a warranty of long service and very small upkeep cost.

This trade-mark guarantee is on every piece of

D. K. McLaren's

Genuine British Oak-Tanned

Leather Belting

It will be to your interest to buy this belting, because it will keep you FREE from belting troubles that are inseparable from inferior belts, such as breakdowns, loss of power, slippage, stretch, etc.

The secret of the success of this belting lies in the fact that it is under the supervision of experts, from the selection of hides till the final finishing touch (the trade-mark) is applied — and that our genuine British Oak method of Tanning makes leather exceptionally tough, durable, and pliable.

Let us send our Catalogue and put you in touch with users.

1888-1914
The Leading Builders of Cotton Gins.
A very severe service because of

GRIT, DUST AND HIGH SPEED

GULLETT GIN COMPANY
Manufacturers
COMPLETE COTTON GINNING OUTFITS.

P.O. Amite, La., Feb. 4th, 1888.

Gentlemen:—We are using your MAGNOLIA METAL in our Magnolia Gins, Feeders and Condensers to our entire satisfaction.

We have adopted Magnolia Metal as the standard anti-friction compound for our machinery, believing it superior to any we have heretofore used.

Yours truly,
GULLETT GIN CO.
Geo. A. Peete, Mgr.

GULLETT GIN COMPANY
Manufacturers
COMPLETE COTTON GINNING OUTFITS.

Gentlemen: P.O. Amite, La., Feb. 26th, 1914.

It gives me pleasure to state that Magnolia Metal is used by us in all high-speed bearings throughout our line of cotton ginning machinery and has given our customers as well as ourselves excellent results. We wish to state further that we have not had a single complaint where Magnolia Metal has been used.

We are also pleased to say that we use nothing but MAGNOLIA METAL to repair bearings of our high-speed wood-working machinery in our wood-working plant, which consists of about forty-five wood-working machines ranging in size from a 12x30" S.A. Woods Timber Sizer down to a 12" hand jointer, embracing quite a number of different types and makes, bearings in some of which have been running almost continuously 3500 R.P.M., ten hours per day, for five years, and show little or no perceptible wear.

Very truly yours,
GULLETT GIN CO.
T. E. Johnson, Supt.

De Laval Class "C" Turbine, directly connected to 1 KW Direct-current Generator.

Efficient and Practical Small Turbine-Exciter and Lighting Sets are Made Possible by the

DE LAVAL Class "C" Turbine

The turbine, which is mounted on the same bed plate with the generator, contains only few and simple parts and requires no further attention than the occasional filling of the oil wells.

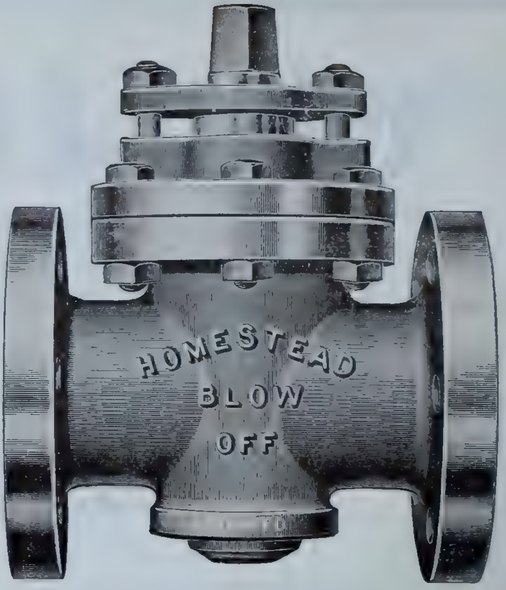
The speed is controlled by a powerful and simple governor, of the same design as that long used on DeLaval Single-Stage Turbines. In addition there is an emergency governor which trips an auxiliary valve in the steam supply line in the event of overspeeding. Damage to surroundings or wheel case is prevented, in case of accidental failure of both governing devices, by a steel armor ring entirely surrounding the wheels.

These small turbines, utilizing the velocity-multi-staging principle, are simple, rugged and reliable and give high economy.

For further particulars regarding De Laval Type "C" Turbines for driving centrifugal pumps and blowers and direct and alternating current generators, send for our Catalogue C61.

DE LAVAL Steam Turbine Co.

Trenton 70 **New Jersey**



Homestead Valves are Quality Valves

A quarter turn—just a slight twist of the wrist—closes or locks the *Homestead.* A quarter turn back opens it wide. It being free from friction, long life and the maximum of service is assured. This valve cannot jar open—when you lock it, it stays locked. The seats are perfectly protected from wear both when closed and when pressure is passing through them. *Every valve* is hand ground to a perfect fit and tested before shipment. They are absolutely leak-proof under any steam, air or hydraulic pressure. *Homestead Valves* are giving satisfaction throughout the entire world, under the most severe conditions. Just try one if the valves you are now using are weak in some essential point. The many superior points of *Homestead* Straightway, Three-way and Four-way Valves fully described in our catalog. CLEAN OIL

Bowser 7F Type Oil Clarifying Outfit, Intended for use in small plants which have comparatively small amounts of oil drips to handle. Other Individual and Central Oil Clarifying Systems at rated capacity of from 5 to 6000 U. S. gallons or more per day.

Oil Money Saved!

A Bowser Oil Filtering and Circulating System is sort of brother to the compound engine. Where the latter permits the use of the same steam more than once, a Bowser System enables you to use the same oil over and over again.

In a Bowser System the quality of the oil is always kept uniformly high. It is all utilized. There can be no leaks—no waste—no loss any way. The great saving and added efficiency quickly repay the cost.

BOWSER ESTABLISHED 1885 **Oil Filtering and Circulating Systems**

For twenty-nine years Bowser has been making oil storage systems to meet every known requirement. Today there are five hundred different Bowser Systems—a million users.

Bowser Systems range from simple Individual hand filtering units to complete yet equally simple Central oil clarifying systems.

What They Do

Reduce friction to the absolute minimum. Provide stream feed in the highest sense of the term. Reduce fire hazard. Save time and labor of men. Save storage space. Compel accuracy and care on part of employees. Make every drop of oil usable **over and over again.**

For Your Needs

Let Bowser confer with you about **your** oil storage needs. Twenty-nine years of such experience may mean something to you. Ask questions. Tell something of your requirements. No cost in finding out. No obligation.

Write today—NOW.

DE LA VERGNE REFRIGERATING MACHINERY

is the standard of the world in the field of refrigeration. De La Vergne machines have been installed in all parts of the world.

We have been building refrigerating machinery for thirty years and **many of our machines installed over twenty years ago are to-day maintaining their high initial performance.**

Our long experience in this particular work enables us to furnish the best design equipment.

We are prepared to furnish everything in the refrigerating line for Breweries, Cold Storage Plants, Packing Houses, Skating Rinks, Ice Plants (distilled or raw water systems), etc.

The name **De La Vergne** stands for **highest quality, maximum capacity, absolute reliability** and **permanent economy.**

Durability is Reliability

Durability saves costs in repairing.
Reliability saves costs in accidents.
Both save costs due to shutdowns.

To have the peace of mind and confidence that the owner of a **FRICK** Machine enjoys during the rush season in midsummer you must be the owner of a **FRICK Machine.**

It costs a little more, but it's cheapest in the end.

It is built with but one aim in view—to make it as durable and reliable as a refrigerating machine can be made. If a weakness develops in the smallest part it is immediately removed—no part is left to chance. Every part is made very heavy and the best materials known are used in its construction.

The result—a machine having the highest degree of durability and reliability—the best for its purpose—the cheapest and safest.

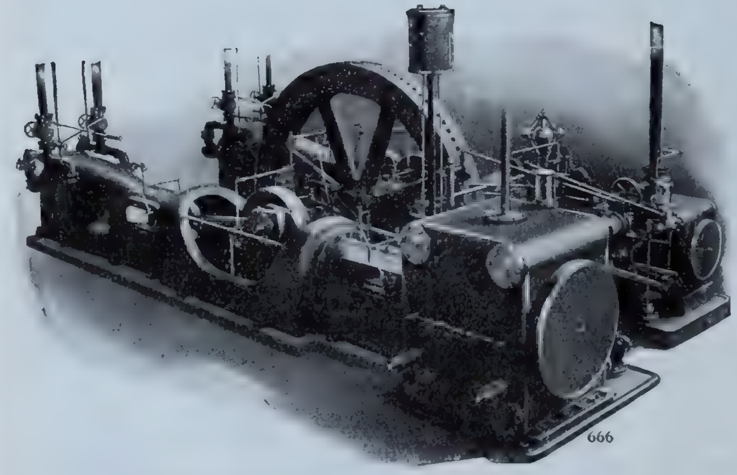
York Horizontal Double-Acting Refrigerating Machines



York Horizontal Duplex Machine (Latest Design).

are well made—from the selection of raw materials to the final test of the finished Machine. There is a pride and pleasure in knowing that your work is well done.

Our Horizontal Double-Acting Refrigerating Machine is a good example of what can be accomplished with carefully selected materials in the hands of expert designers and skilled mechanics.

Solid cranks and pins of cast steel; nickel steel piston rods and wrist pins; cast steel crossheads; solid compressor frame, eliminating tie rods; accessibility of suction and discharge valves; method of stuffing box alignment;—are features of our standard construction, to which we call especial attention.

Telescopic Oilers and central oiling system are refinements which we furnish when required.

Built in various sizes from 20 tons refrigerating capacity and upwards, either belt or steam-driven, with simple or compound engines.

THE H&C SAFETY

SAFETY FIRST!-

Economy, Durability, Efficiency

ALWAYS

This is the whole secret of the

"H. & C. Safety" Success

The strongest single proof of the "H. & C. Safety" Compressor's ability to give you a profitable year in—year out service is the list of growing, successful concerns using the "H. & C." System.

Our repeat orders for additional equipment to supply the increasing demand of our old customers—customers who are already operating one or more "H. & C. Safety" machines and know their strength, simplicity and capacity is a big business in itself.

And it's business we are particularly proud of—this re-order business. Because it proves absolutely that the "H. & C. Safety" has given a big "value received" or we would never have gotten the invitation to do it again.

Write for our booklet on "Cold Facts."

Pratt & Cady Valves

with Renewable Bronze Seat Rings

Those who are looking for a valve of the highest grade, one which they can rely upon to help in their "Safety First" campaign, will do well to choose the P. & C. line of gate valves, made in Brass and Iron from 1¼" up; they all have the same

Retaining Ring Construction

The seat rings are independent rings of bronze, or any special metal or material best adapted for the service in which the valve is to be used. These seats can be renewed by removing the retaining rings with a suitable wrench made for the purpose, or other appropriate tool. The gate is a double-faced, wedge-shaped casting, with side grooves by means of which it slides on guides in the valve body.

Great pains are taken in the machining of all parts of these gate valves. Gauges are used on each part to insure their accuracy and interchangeability. The guides in the bodies are of equal thickness, and the wedges can be taken out of the valve and replaced with the opposite faces in contact, and will give an accurate fit. The importance of this in making repairs is obvious. These valves being double-seated can be used with the pressure applied at either end.

For Superheat and High Pressure, Wet Steam and Oil, use Durabla Packing.

Light and Power Companies, Large Corporations, Industrial Plants, Mining and Smelting Companies, Department Stores, Hotels, Office Buildings, Electric and Steam Railroads, Steamships, U. S. Government, and many other classes of users are reducing fuse Maintenance expense over 80 per cent. by using

ECONOMY RENEWABLE FUSES

They use Economy Renewable Fuses for these reasons:

First, of course, because it provides a practical method of reducing the fuse maintenance expense more than 80%.
Second, because it is the only renewable fuse that is uniformly rated.
Third, because it is the only design so far produced that provides the desired electrical characteristics.
Fourth, because all capacities of renewal elements are readily available, making large fuse stocks unnecessary.
Fifth, because they never vent fire or hold a sustained arc and are absolutely safe.
Sixth, because they meet the performance specifications governing the use of such devices.

Special Announcement!

Two Economy Renewal Elements are now furnished (without charge) with each Economy Fuse. Now YOU figure what fuse is the cheapest not only to buy but also to maintain.

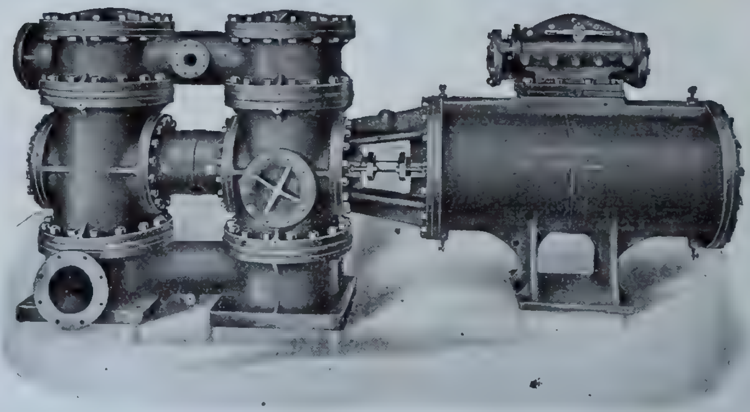
Tests Proved More than Claims of Bawden Pumps on Toronto Fire Tug

The Bawden Compound Pump installed by us on the steamer "Clarke" for fire service on the Toronto water front proved the Bawden pumps to be all and more than has been claimed for them regarding efficiency and service.



The Pump has:

- 14" diam. High-Pressure Steam Cylinder.
- 24" diam. Low-Pressure Steam Cylinder.
- 12" diam. Water Cylinder.
- 20" Stroke.
- And is of the Group Valve Type.

On the tests made by Fire Chief Thompson at Centre Island on May 13th, the pump was operated by 80 H.P. boiler carrying 150 lbs. steam pressure and the pump delivered 1,000 U.S. Gallons per minute against 200 lbs. pressure and with two 750 feet lengths of 2½" fire hose fitted with 1¼" nozzles and delivered two streams 124 ft. high.

The results given, as in all Bawden installations, proved Bawden pumps to be all that is claimed for them.

Electric **Boiler Scale Picking Machine,** Devoorde's Patent

Type F: For Fire-tube Boilers, etc., also for Picking the Grates Crusts, etc. For Cleaning Ship's Skins and for Sharpening Millstones.

Type R: For Cleaning the Tubes of Watertube Boilers, Steeptube Boilers, Economizers, Vacuum Apparatus, etc. (also suited for narrow and slightly curved tubes).

Type C: Combined installation.

Splendid Testimonials at Disposal! Great Advantages!

Approved where other Types Failed

Enormous Capacity!

Extraordinarily Simple Design

Design many hundred times approved, also under unfavorable boiler scale conditions.

OPERATION:

The three Pickers strike about 7200 times a minute and at the same time exert a tearing effect. The Pickers are pivoted and their action is elastically damped in a natural manner by the centrifugal force, they therefore operate free of all shocks, require very little power, do not fatigue, do not wear the edges of the pickers, **do not burr** and will also clean inaccessible parts.

Beware of inferior imitations.

Bader & Halbig, Halle a. Salle (Germany)

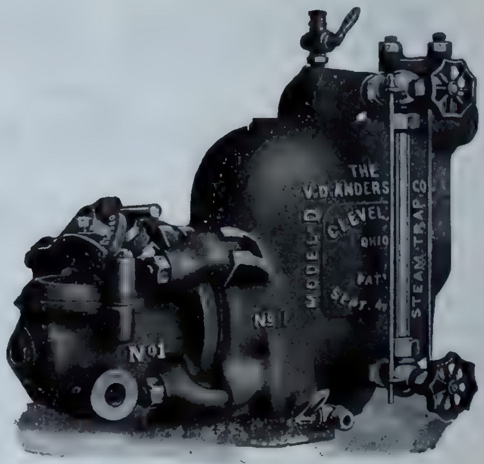
Enormous Capacity!

Easy Manipulation.

Small Consumption of Current.

In use with Railways, Shipbuilders, small and large Industrial Plants.

The Anderson Model "D" Steam Trap



Is a steady and continuous drainer, and automatically adjusts itself to any varying amounts of condensation within its capacity.

It prevents the trouble that usually occurs from faulty testing systems.

It is constructed so that you can change the Valve and Valve Seat from high to low pressure in five minutes, without unscrewing steam joints or pipe connections.

All parts are machined to solid gauges, insuring absolute accuracy, and are interchangeable.

A removable perforated strainer is part of the equipment. This prevents pieces of scale, packing lead, etc., from entering the trap.

Every trap is tested and inspected under boiler pressure by experts before leaving the Factory.

Every Anderson Model "D" is guaranteed.

Write for Booklet. It gives full details.

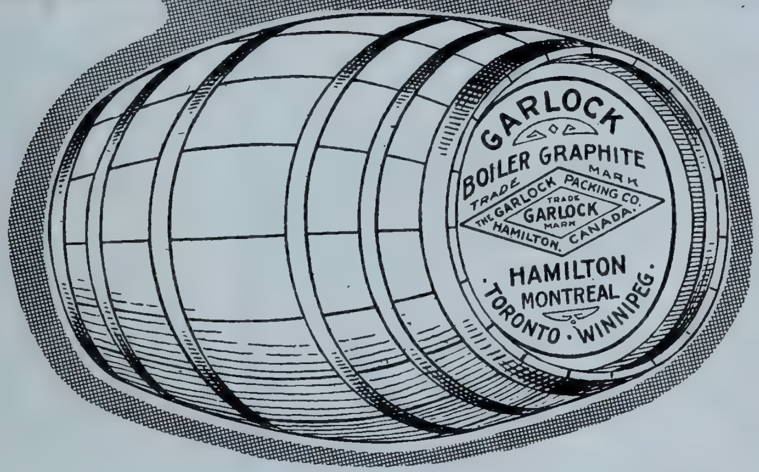
The Firm That Put the "phite" in Graphite

Garlock

BOILER GRAPHITE



One of the Most Successful Scale Fighters on the Market

It's the Method of Attack that Does the Trick

It circulates with the water through the boiler, will attack, soften and so disintegrate old scale that it may be easily removed, and will impart to the steel of the boiler a graphite finish on which new scale will not readily form. What little does form will be soft and so mixed with graphite as to be easily removed.

There is a mechanical—not a chemical action. It will not injure the tubes in the slightest degree.

By using Garlock Boiler Graphite you will increase the efficiency of your boiler, reduce fuel bills and easily clean your tubes.

To prove the effectiveness of this boiler graphite, we will send you a barrel on 60 days' trial. Keep it if you like it. If not satisfactory at the end of this trial period, return the unused portion at our expense and there will no charge for quantity used, nor expense to you in any way.

Fair Proposition?

The Garlock Packing Co., **HAMILTON ONTARIO**

MONTREAL TORONTO WINNIPEG CALGARY

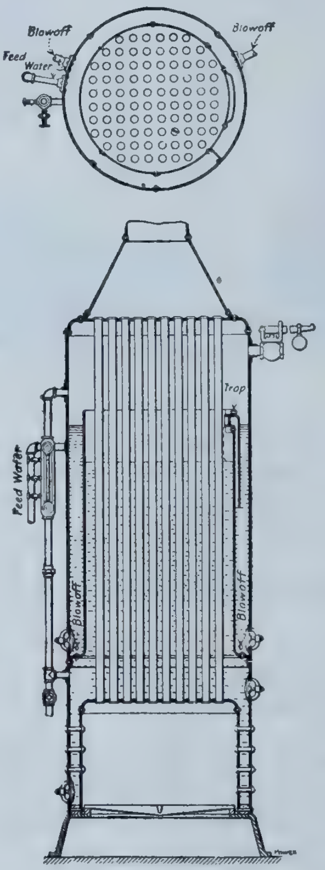
An Invention A fool-proof and scale-proof BOILER

THE ALEX. McKAY BOILER WORKS, Boiler Manufacturers of Montreal, are manufacturing a Scale-Proof Boiler which settles satisfactorily the scale problem. This firm, throughout its long experience, recognizes the fact that the only definite way to do away with this ever-present trouble was, not to depend upon the engineer's doubtful knowledge of treatment of hard waters or his skill and reliability in periodically cleaning boilers, but to make the boiler itself fool-proof.

The ingenious way in which this has been accomplished is shown in the accompanying illustration. The boiler is of the internally fired, vertical, full length tubular type and of the best design and, in addition to the usual attachments, is provided with a scale chamber. This arrangement consists of a flanged ring attached to the inside of the shell above the lower tube sheet. To the inner flange of the ring a casing is attached and extends a little above the normal water line of the boiler, thus forming an annular space between the outer shell into which the water enters.

On top of the side opposite the feed inlet is cut a notch or weir; over this notch a hood is placed which extends to the level of the top of the chamber and 15 inches below the top of chamber, so that only pure water can flow over into the tube chamber and come into contact with the heating surface. The process is as follows: The feed water enters and fills the scale chamber to the point of overflow into the boiler. The capacity of this space is proportional to the size of the boiler and is sufficient to allow the complete precipitation of all scale-forming material before the water goes to the boiler proper. While in the scale chamber its temperature is raised to that of the steam, which is usually above 300 F. The carbonates are mostly precipitated at 200 F. and the sulphates at 280 F. in the form of a soft sludge, which is periodically blown off at the bottom of the chamber and cannot become baked hard as it would if in contact with the heating surface or the hotter parts of the boiler.

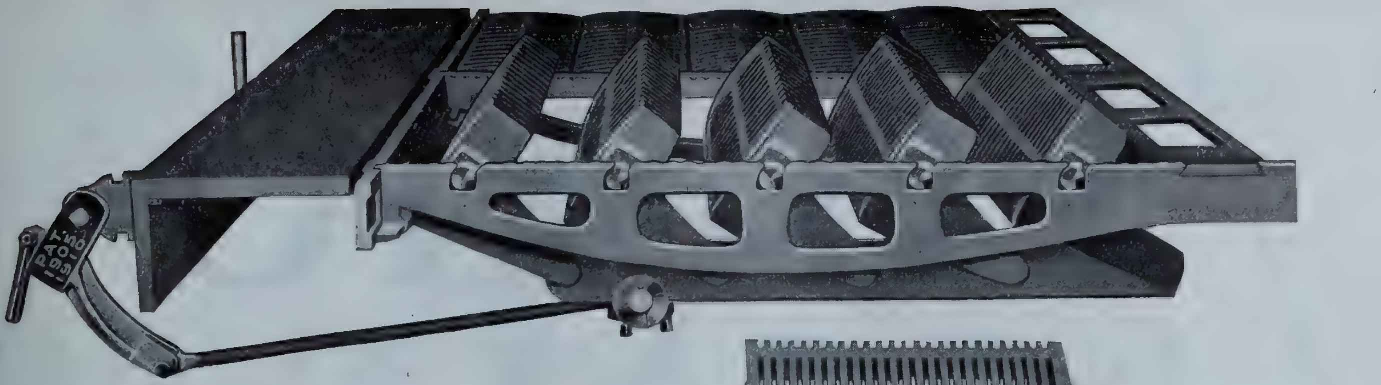
The success of this simple arrangement after years of use has been much greater than anticipated when it was first put upon the market. As a test, 20 lbs. dry earth, 20 lbs. lime, and 10 lbs. plaster of Paris, making a mixture like milk, was fed into the boiler, and after shutting down all the solid matter was found in the scale chamber.



Engineers are beginning to realize that the vertical, full length tube boiler, made sufficiently high so as to give a large heating surface, is the best boiler. The tubes in such a boiler give effective heating surface from the crown sheet of the furnace to the top head of the boiler, inasmuch as the whole inside surface of the tubes are in direct contact with the hot gases from the furnace. Contrasted with the horizontal fire and water tubular boilers, it will be seen that the conditions are not the same, as in either of these type of boilers only that portion of the tubes in contact with the heat from the furnace is effective heating surface. The amount of heating surface available for the superheating of steam in the vertical, full length tube boiler, makes same very economical. The old question will arise amongst engineers, that vertical, full length tube boilers have to be cleaned the same as all other types and, that in raising steam again with only cold water in the boiler, the top ends of the tubes may be overheated, but remember, with our Scale-Proof Boiler, you don't have to blow your boiler down, as you have to do in all other cases; you simply open the Scale chamber, blow off once a day, and blow 'all scale-forming matter out, boiler in meantime being under full head of steam.

The value of the Scale-Proof feature can hardly be fully realized, particularly when applied to portable machinery which is handled by all types of engineers and is subject to all kinds of water conditions. The saving of coal and all materials and apparatus for the treatment of hard water, as well as the labor of scraping out scaly boilers, are as much appreciated by the fireman as by the owner of the plant. The saving of fuel, feed water purifying apparatus and compounds alone ought to recommend such a boiler as a time and money saver.

The manufacturers of this patented boiler, The Alex. McKay Boiler Works, whose plant and offices are at 1194 Demontigny Street East, Montreal, have had a long and successful career as boiler builders, and invite inquiries and will be pleased to give further particulars, prices, etc., to interested parties. Address all correspondence to The Alex. McKay Boiler Works, Boiler Dept., 1194 Demontigny Street East, Montreal, Que.



CYCLONE

Shaking and Dumping Grates

effect a great saving in fuel because with them screenings or any grade of hard or soft coal can be burned with results equal to that of the best.

This construction means highest efficiency and long life.

There is an **exclusive shaking feature** possessed by no other Grate Bar. It means more vigorous and effective shaking, which is invaluable, and can be explained by any user.

The 68% air space and 90% underdraught means very complete combustion.

Any of the users listed herewith will be glad to tell you all about the "Cyclone." Why not write them?

We are prepared to instal our Grates in the Plant of any respectable Company on **30 days' trial.** If satisfactory, we will expect payment as agreed on, and if not, we will remove the Grate from the premises without cost or lost time to the purchaser.

Beware of imitations — they won't give the service.

POTATO SCALE

BOILER CLEANSER

Survival of the fittest

Potato Scale stops boiler-destructing and fuel-wasting as soon as Potato Scale Boiler Compound comes in contact with it.

The two cannot live in the same boiler, and the latter is the stronger.

While this Compound, used in smaller quantities, proves disastrous to scale, it has not the power to cause the slightest injury to tubes or fittings.

We treat each case individually, and guarantee satisfactory results.

We'll be pleased to send a trial keg.

Satisfaction or no pay, and to put you in touch with users.

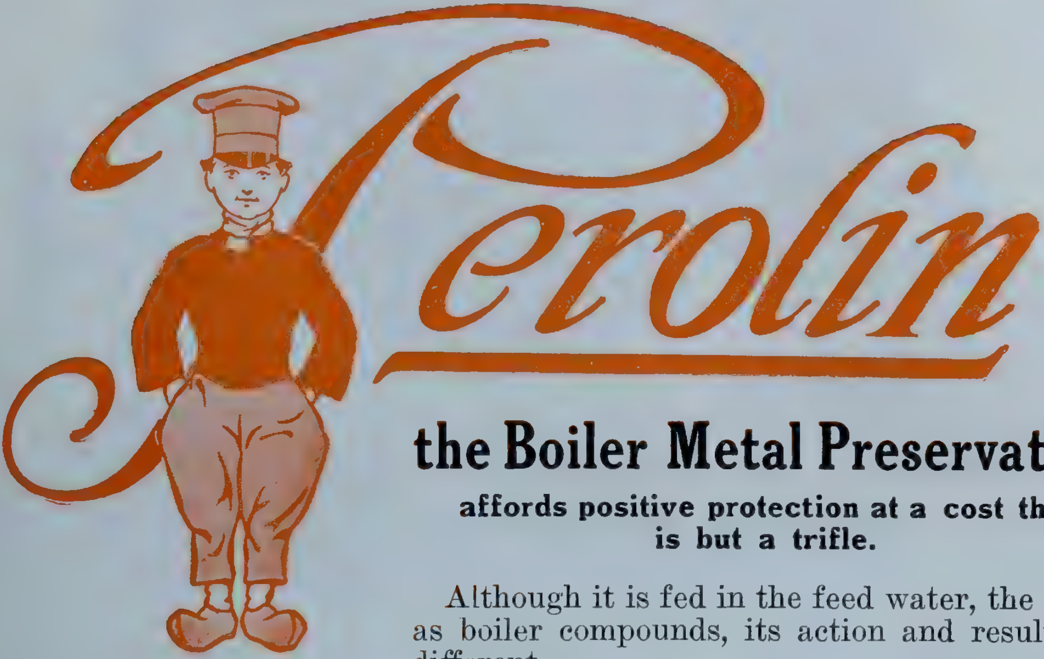
Boiler destructing ingredients prevail in all feed water— therefore it is practical economy to protect the boiler.



the Boiler Metal Preservative

affords positive protection at a cost that is but a trifle.

Although it is fed in the feed water, the same as boiler compounds, its action and result are different.

If the tubes are coated with scale, Perolin works through the cracks in the latter (which are caused by expansion and contraction of boilers) to the metal—and works along the metal, loosening the scale mechanically so that it can be readily washed out.

Perolin forms a preservative film over the tubes and shell, when old scale is removed. This film prevents scale-forming substances from adhering, and prevents pitting, corrosion, etc.

The preservative film is an efficient transmitter of heat; it keeps the boiler at full rated capacity, and as a result an enormous saving in fuel is effected.

The Bureau of Inspection, Tests and Consultation says that **Perolin will not injure metal.** Will send you a copy of their letter if you wish.

By using Perolin you will save much time and labor.

It is used in over 20,000 plants in Canada, United States and Mexico, and throughout Europe—everywhere the demand is rapidly growing because Perolin always makes good.

We'll ship you, freight prepaid, a sufficient quantity to test for sixty days. REMEMBER — if not satisfied with the result—return what you have left, and the amount used will cost you nothing.

GUARANTEE

We guarantee PEROLIN, the German Boiler Metal Treatment

1. To loosen scale already formed in the boilers by its mechanical action;
2. To Prevent New scale from forming;
3. To protect the boiler metal against pitting, corrosion and galvanic action, regardless of the kind of water used;
4. To correct troubles caused by oil and grease getting into the boiler water;
5. Not to affect or impart any off-odor to steam or distilled water, or affect in any way the products of breweries, ice plants, dye-works or other industries using live steam for cooking or manufacturing;
6. That PEROLIN is not a boiler compound for water treatment, but operates independent of water conditions;
7. The PEROLIN preservative liquid film is a good heat conductor, adding to the efficiency of the boilers;
8. The establishment of the PEROLIN protective film in new boilers will prevent all scale formation and corrosion, thus keeping the boilers up to their full rated capacity.

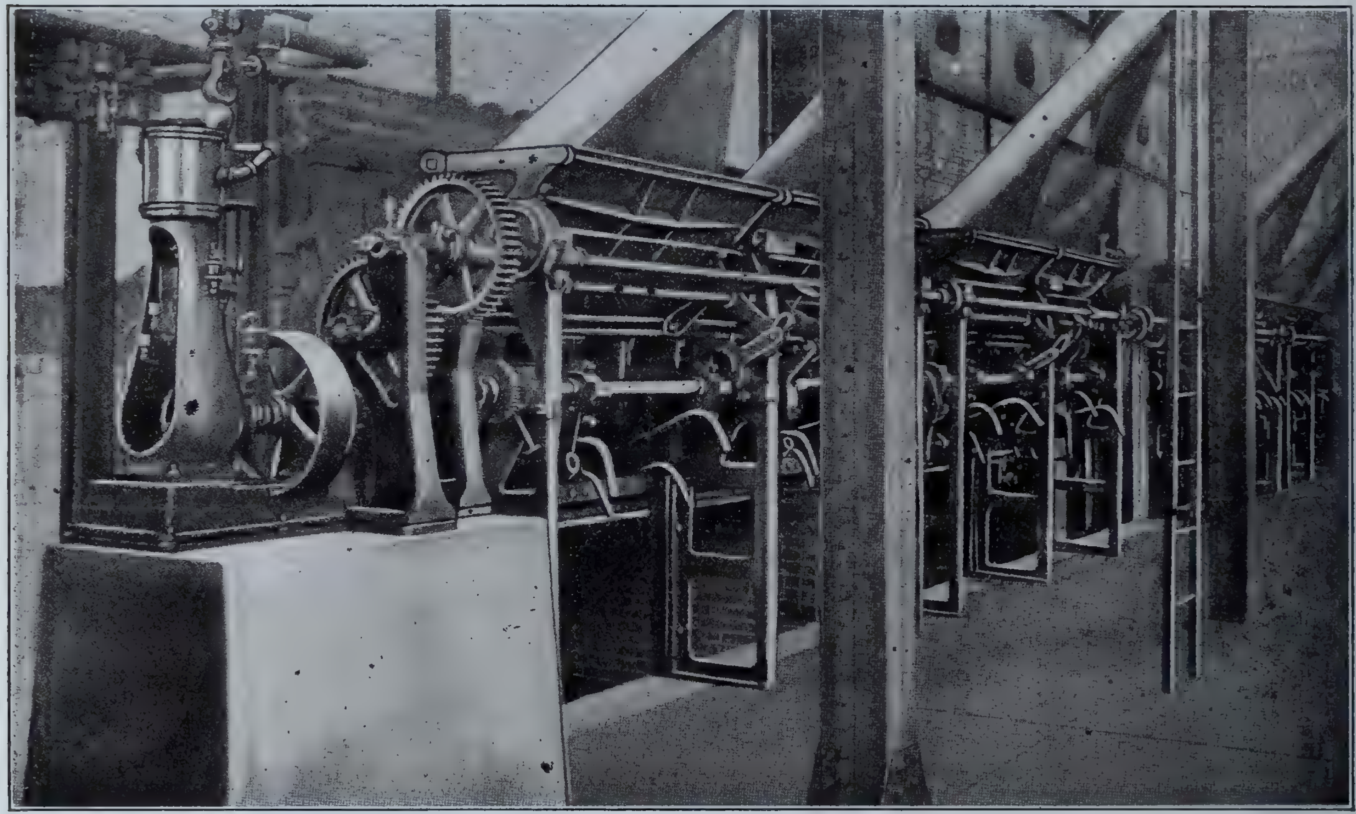
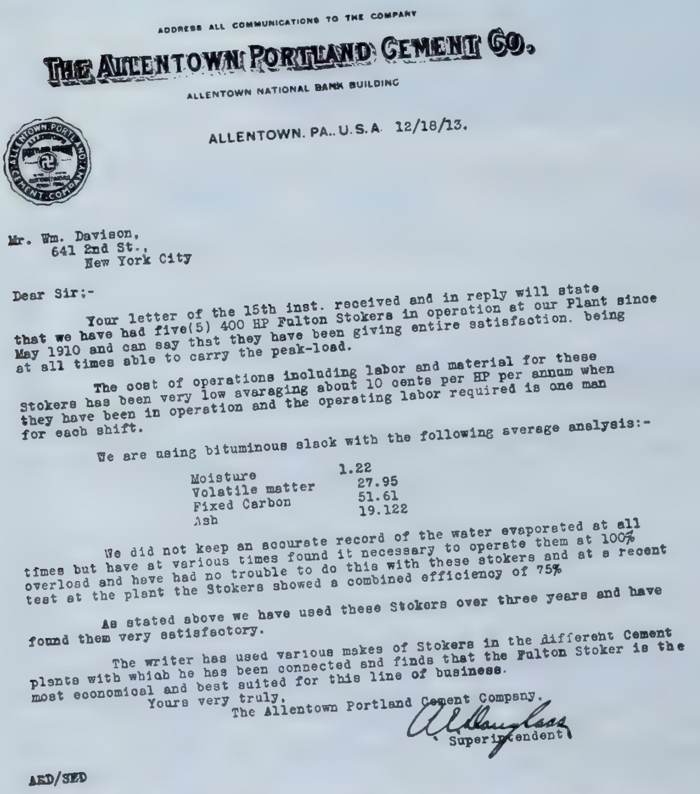
FULTON WATER-COOLED MECHANICAL STOKERS



5-400 H.P., No. 12010, Type "H," Fulton Water-Cooled Mechanical Stokers installed in the Plant of The ALLENTOWN PORTLAND CEMENT COMPANY Evansville, Pa.



ADDRESS ALL COMMUNICATIONS TO THE COMPANY
THE ALLENTOWN PORTLAND CEMENT CO.
ALLENTOWN NATIONAL BANK BUILDING
ALLENTOWN, PA., U.S.A. 12/18/13.

Mr. Wm. Davison,
641 2nd St.,
New York City

Dear Sir;-

Your letter of the 15th inst. received and in reply will state that we have had five(5) 400 HP Fulton Stokers in operation at our Plant since May 1910 and can say that they have been giving entire satisfaction. being at all times able to carry the peak-load.

The cost of operations including labor and material for these Stokers has been very low avaraging about 10 cents per HP per annum when they have been in operation and the operating labor required is one man for each shift.

We are using bituminous slack with the following average analysis:-

Moisture	1.22
Volatile matter	27.95
Fixed Carbon	51.61
Ash	19.122

We did not keep an accurate record of the water evaporated at all times but have at various times found it necessary to operate them at 100% overload and have had no trouble to do this with these stokers and at a recent test at the plant the Stokers showed a combined efficiency of 75%

As stated above we have used these Stokers over three years and have found them very satisfactory.

The writer has used various makes of Stokers in the different Cement plants with which he has been connected and finds that the Fulton Stoker is the most economical and best suited for this line of business.

Yours very truly,
The Allentown Portland Cement Company.
A L Douglass
Superintendent

AED/SED

NOTE THE RESULTS

Efficiency:—75% Combined efficiency Boiler and Stoker.

Capacity:—100% continuous overload secured at any time desired, or 800 horse-power per unit.

Repairs:—Four of these units have been in continuous operation 24 hours per day, and 365 days per year, for 3 years and 9 months. This is equivalent to 10.95 years' service of 3000 hours each. 17,520 H.P. years, repairs $600 from all causes (material and labor) or **2.92 cents** per Horse-Power per Year.

Jones Underfeed Stokers

In Pulp and Paper Mills

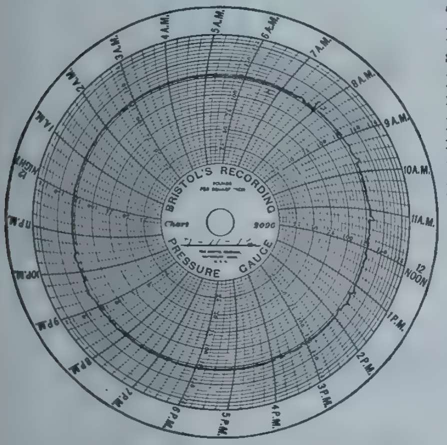
have made possible fuel savings never before credited any system of firing.

Take as illustration the boiler plants of the Minnesota & Ontario Power Company, Fort Frances, Ontario, and International Falls, Minnesota:

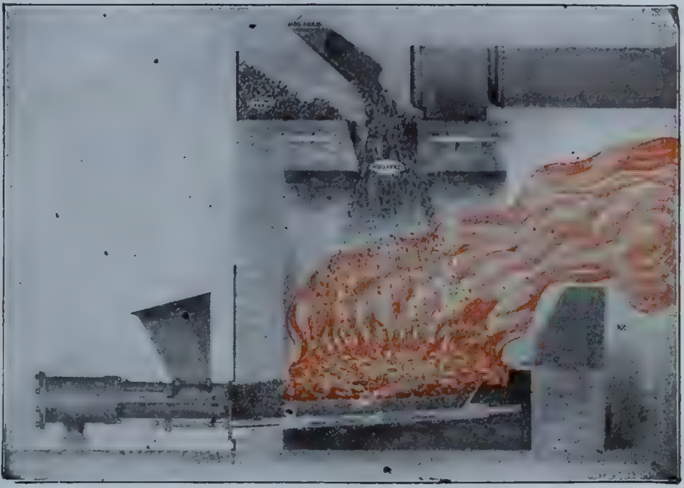
Before the stokers were installed in the latter plant 3,000 tons of coal were required each month, costing them nearly $3.50 per ton. Since installing Jones stokers, under normal conditions, only five tons of coal are burned per week, the balance of heat required being obtained from "hog feed" and paper mill refuse—heretofore a waste product, entailing an enormous and continual expense for its disposal.

The saving is, therefore, 3,000—22=2,978 tons @ $3.50=$10,423.00 per month, or more than $300.00 per day.

The equipment is entirely automatic, and should a drop of a few pounds occur in the steam pressure, or should there be a shortage in the supply of refuse, the stokers immediately feed in more coal and the blower equipment supplies more air, so that the normal pressure is promptly restored. If for any reason the "hog feed" is temporarily abandoned, the stokers automatically make the change over, carrying the load with coal alone.



The steam chart here illustrated shows the constant pressure that is maintained in this plant burning "hog feed" or refuse mixed with a small proportion of coal.



Arrangement of Jones Underfeed Stokers in Dutch Oven for burning paper mill refuse in conjunction with coal.

If you have refuse to burn or if you have a steam plant to fire on coal alone, you need a Jones Stoker equipment just as much as did any of the following Paper Mills having boilers Jones Stoker equipped:

THE MURPHY AUTOMATIC SMOKELESS FURNACE

Home of the Murphy Automatic Smokeless Furnace, largest plant in the world devoted exclusively to the manufacture of "Automatic Furnaces."

Users of MURPHY FURNACES have the REPEAT ORDER HABIT; for example: CANADIAN KODAK CO., LTD., Toronto, Ont.

FIRST ORDER, Oct., 1908; SECOND ORDER, Apr., 1914; 8 furnaces, 1,720 H.P. The parent Company—EASTMAN KODAK CO., Rochester, N.Y., has had eight years' experience; FIRST ORDER, 1906; FOURTH ORDER, Feb., 1911, 20 furnaces, 6,700 H.P.

LAURENTIDE PAPER CO., LTD., Grand Mere, P.Q.
FIRST ORDER, 1905; FOURTH ORDER, May, 1912; 14 furnaces, 4,300 H.P.

BELGO CANADIAN PULP & PAPER CO., LTD., Shawinigan Falls, P.Q.
FIRST ORDER, 1910; FOURTH ORDER, March, 1914; 8 furnaces, 2,470 H.P.

HARRIS ABATTOIR CO., LTD., Toronto, Ont.
FIRST ORDER, 1909; THIRD ORDER, Dec., 1912; 6 furnaces, 1,650 H.P.

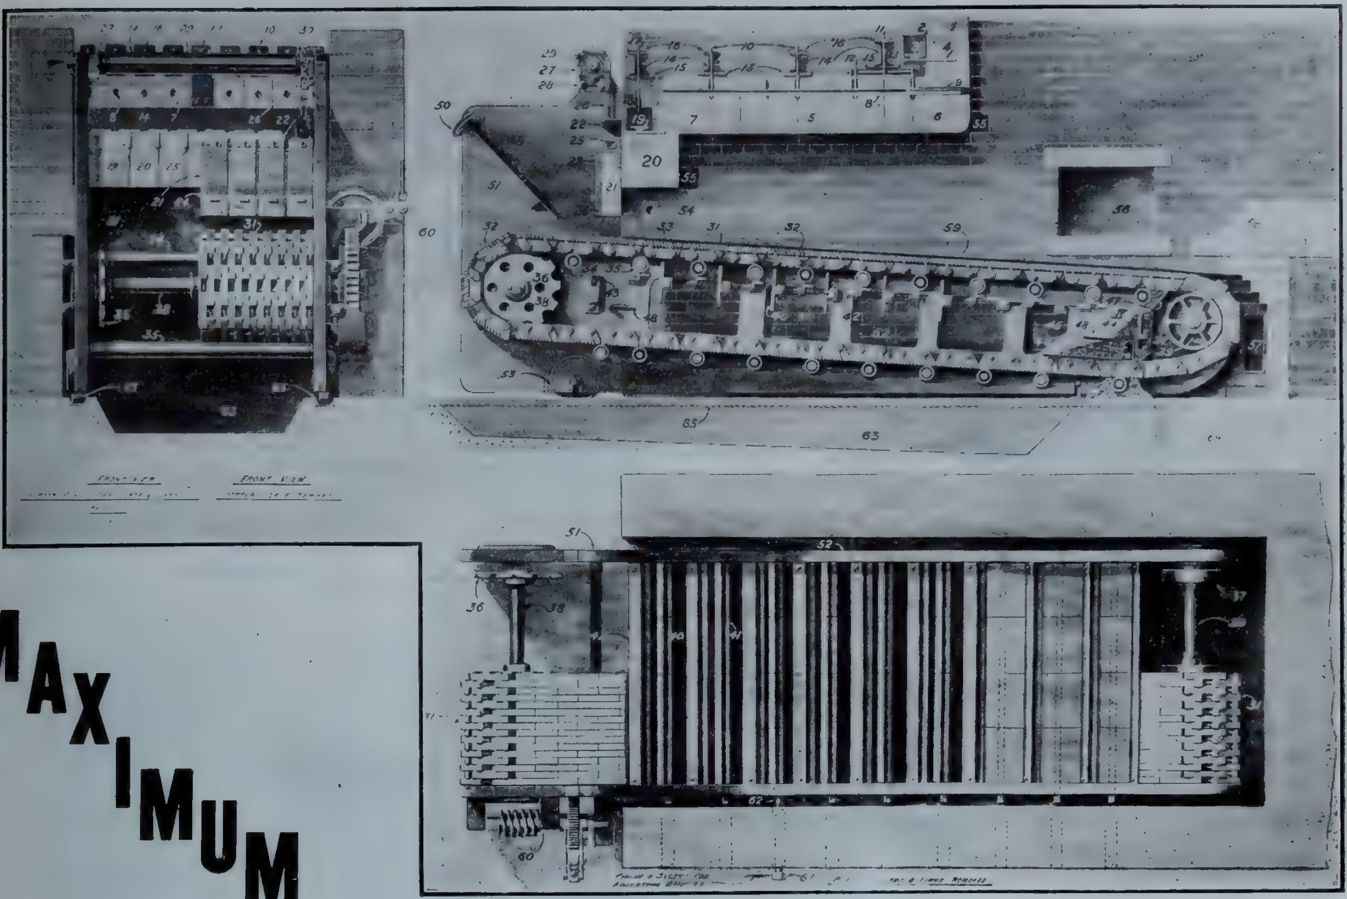
ST. LAWRENCE STARCH CO., LTD., Port Credit, Ont.
FIRST ORDER, 1908; THIRD ORDER, June, 1913; 8 furnaces, 1,460 H.P.

Determine 20 per cent. of your annual coal bill and you will approximate the dividend earning power of money investment required for MURPHY FURNACES.

Complete descriptive catalogue upon application.

Murphy Iron Works

Detroit, Mich. **Buffalo, N.Y.**



MAXIMUM FURNACE EFFICIENCY

PERFECT IGNITION AND SMOKELESS COMBUSTION.

Our high arch insures free flame propagation, which raises the temperature of the short ignition arch, and reflects heat where it is required for raising the temperature of the coal to its burning point. These conditions preclude the possibility of coal entering the furnace a foot or more without catching fire, a failing common to many chain grate installations. The high temperature at front of furnace affords early opportunity for burning the smoke-producing gases which are evolved, and they leave the furnace colorless.

PROPER AIR DISTRIBUTION.

By means of dampers under the chain, air can be admitted to any portion of the grate desired, and thus any load from a banked fire to 250 per cent. of boiler rating can be carried without any excess of air.

ADJUSTABLE COAL FEED.

The stoker can be run at five speeds, and in addition the depth of full bed can be varied by means of a movable gate.

MINIMUM UPKEEP.

The links are of a length proven best for resisting the destructive action of the fire. A broken link could, however, be easily and quickly replaced by a repair link. The chain rods are cylindrical, and expose all their surface to equal wear. Round rods eliminate the danger of links becoming locked in a cramped position.

Whether your plant is large or small, the Illinois Chain Grate Stoker means practical economy and maximum results.

Write for full details.

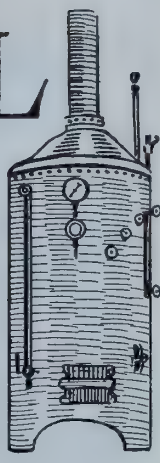
BOILER ROOM ANNUAL

THE POWER HOUSE

JUNE 1914



Power, Light and Heat in the C.P.R. Office Building, Toronto

Staff Article

The equipment installed in the new C.P.R. office building in Toronto, is an excellent example of an independent layout, and goes to show that given careful attention in individual feature planning, it is possible to secure power, light and heat more cheaply and with equal reliability of service than by outside purchase.

A HANDSOME office building, which until recently was the highest structure in Toronto, has been erected by the Canadian Pacific Railway Co. at the corner of King and Yonge Streets. The building contains several features of interest, the most important to readers of **The Power House** being the power plant, which is complete in every respect. The building was designed by Darling & Pearson, architects of Toronto, and comprises fifteen storeys, in addition to the basement and sub-basement. The ground and first floors are occupied by the C.P.R. themselves, and are used as business offices, while the fourteenth and fifteenth floors are occupied by their telegraph department. The remaining floors are let as business offices.

The power plant is located in the sub-basement, which is thirty feet below the street level. This floor is divided into three sections, comprising the boiler-room, engine-room, and pump-room respectively, while in the basement above are one set of ventilating fans, elevator pressure tanks, wash--rooms for the staff and the telegraph messenger department.

Boiler-Room.

An interesting feature of the plant is the well-equipped boiler-room. The installation comprises three water tube boilers, arranged in one double and one single battery, and supplied by the Babcock & Wilcox Co., through the Toronto office. Each boiler is rated at 160-h.p., and has 1,619 sq. ft. of heating surface. The tubes are 4 in. diameter by 18 ft. long, arranged in nine sections, eight high. The steam drums are 42 in. diameter by 24 ft. long, and the headers and cross boxes are of forged steel construction. The normal working pressure is 160 pounds. The boilers are equipped with **Dutch Oven** furnaces and **Murphy** mechanical stokers, the latter supplied by the Murphy Ironworks, Detroit, Mich.

A modern coal handling plant has been installed. The coal is dumped from the street down chutes into two large steel hoppers located on the west side of the boiler-room and under the sidewalk. The bottom of each hopper is fitted with a door to control the supply of coal to the conveyer running underneath. The conveyer carries the coal from the hopper to the top of the boiler-room, where it is fed into an **Avery** coal weigher, having a capacity of 1,000 pounds. The coal weigher is suspended from overhead tracks, and travels along over the furnaces to deposit the coal. The operations of the weigher are controlled from the floor. The conveyer system is driven by a 5-h.p. C.G.E. motor.

EXTERIOR VIEW OF BUILDING.

All the steam pipes are extra heavy, with **Crane** fittings. The boiler header is 8 in. diameter, branches 6 in., and main steam pipe 6 in. diameter. The steam pipes to the engines are 5 in., 4 in. and 3 in. diameter respectively. All the steam pipes are covered with 85 per cent. magnesia blocks, supplied by the Philip Carey Co., Toronto. In the breeching is a damper which is controlled by a **Spencer** damper regulator. A draft gauge, situated on a gauge board in the engine-room, will be described later.

Engine-Room.

The plant supplies light and power for the building entirely independent of outside supply. There are three direct-connected generator sets, the engines being supplied and installed by the International Engineering Works, Amherst, N.S., and the generators by the Canadian General Electric Co., Toronto. The engines are all of the same type; viz., high speed, horizontal, side crank, totally inclosed, and are fitted with forced lubrication and fly wheel governors. The three units consist of 100 k.w. running at 250 r.p.m, one 75 k.w. at 275 r.p.m., and one 50 k.w. at 280 r.p.m. The generators are all 3-wire, 250-volt d.c. machines.

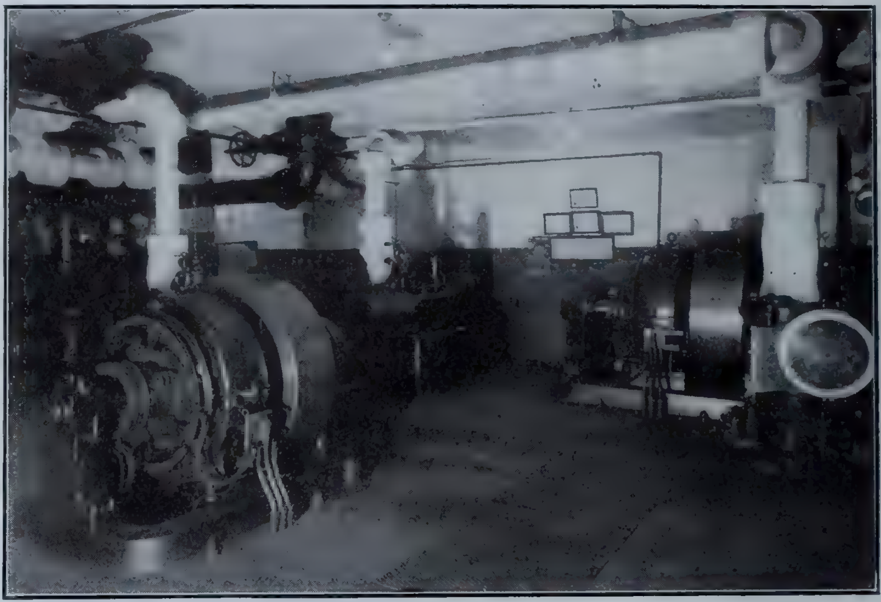
In the engine-room is a gauge board fitted with the following gauges, and supplied by the Jas. Morrison Brass Co., Toronto:—Boiler pressure; vacuum in heating system; compound gauge; altitude gauge, showing the height of water in feet in cold water service pipes; pressure in elevator piping system; pressure in the stand pipes; clock; recording gauge for steam pressure; recording gauge for heating system; recording gauge for vacuum system, and gauge for indicating draft in stack.

A 2 x ¾-in. Venturi meter is installed in the engine-room for measuring the amount of feed water passing to the boilers, while the drips from the various lines are returned to the feed water heater by "**Boylston**" return traps.

Switchboard

The switchboard is made of white marble, and was supplied by the Northern Electric and Mfg. Co., Montreal. There are six panels, consisting of three generator panels, one power panel, one lighting panel, and one low tension panel. Each generator panel has a Canadian Westinghouse circuit breaker, and at the back of the board are three Cutler-Hammer field regulating rheostats. The power and lighting panels are supplied with three "**Sangamo**" type watt-hour meters, and the low tension panels are equipped with one voltmeter and two ammeters of the Weston type, as are all the other similar instruments.

Two motor generator sets are installed in the engine-room for supplying current at 20 volts to a storage battery for the fire alarm and elevator signal system, etc. The sets were supplied by the Diehl Mfg. Co., Elizabethport, N.J. Current is supplied to the motors at 220 volts d.c., and for the electric lighting system at 110 volts d.c. Low tension distributing panels are installed on different floors for controlling the lighting and telegraph, telephone and clock system.



ENGINE ROOM, SHOWING ENGINES AND GENERATORS.

BABCOCK & WILCOX BOILERS WITH MURPHY STOKERS.

Pumping Installation.

The pumps for all services are installed in a section of the sub-basement adjoining the boiler-room. There are two **Deane** boiler feed pumps, 7½-5-6 in., horizontal duplex type, outside packed, double plunger pattern. The pumps are designed to operate against a head of 250 pounds, and are fitted with composition valve seats and disc valves. Two pumps, identical in every particular, care for the hot water service. In connection with this system is a hot water heater located near the pumps and heated by exhaust steam. The heater is fitted with a **Johnson** temperature control device, which automatically maintains the water at about 180 degrees, or as required.

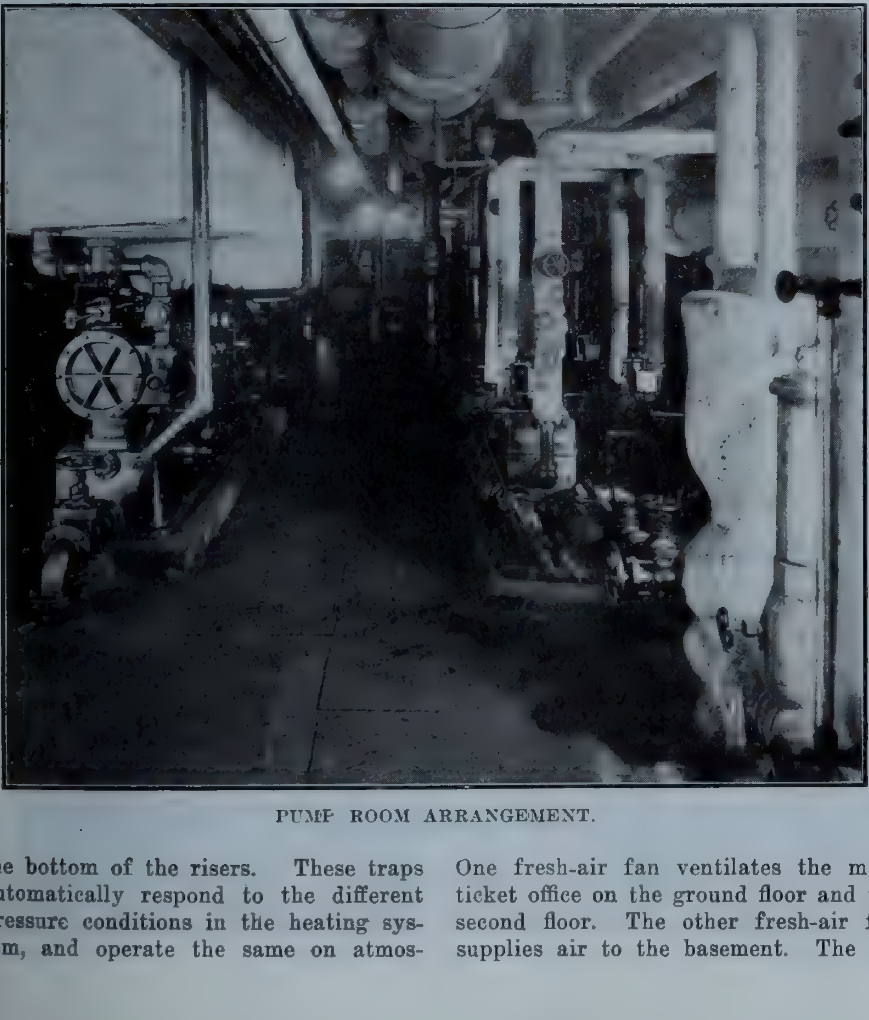
In connection with the exhaust steam heating system there are two "**Deane**" vacuum pumps, 8-12-12 in., double-acting, simplex, horizontal type, and equipped with governors. The receiver for the returns and the oil separator are situated near the pumps. The feed water heater is of the **Webster** type, and was supplied by Darling Bros., Montreal. All the pumps above mentioned were supplied by the Deane Steam Pump Co., Holyoke, Mass. There are two **Smart-Turner** centrifugal sump pumps, driven by 2-h.p. and 5-h.p. Canadian Westinghouse motors. The **Underwriter** fire pump, 14-7½-12 in., has a capacity of 500 gallons per minute at 70 r.p.m., and was supplied by Canadian Allis-Chalmers, Ltd., Toronto. A **Worthington** jack pump, 10-15-10 in., duplex type, is installed in connection with one of the elevators for use when lifting extra heavy freight. This pump gives a pressure of 600 pounds per sq. inch, which will lift a weight of 9 tons in the elevator.

Elevators.

There are four passenger elevators, three operating between the ground and the top floor, and one between the sub-basement and the top floor, the shaft of the latter being 230 ft. long. They are all hydraulic plunger type elevators, and were installed by the John McDougall Caledonian Ironworks Co., Montreal. Two **Worthington** steam pumps, located in the engine-room, supply the necessary power, 185 pounds being the working pressure. The pumps are horizontal tandem compound duplex type, 16-25-12-18 in., and pump water from a storage tank into two pressure tanks, located in the basement, each tank having a capacity of 5,000 gallons. Pressure is maintained in the pressure tanks by an air pump supplied by the American Air Pump Co. The elevators are controlled by "**Larsson**" valves of the latest pattern and equipped with four distinct safety devices, so that it is practically impossible for an accident to occur. Lamp signals are provided in the elevators, and operated by push buttons on each floor. The elevator enclosures were furnished by the Architectural Bronze and Ironworks of the Canadian Allis-Chalmers Co. Crane valves and fittings are used here throughout.

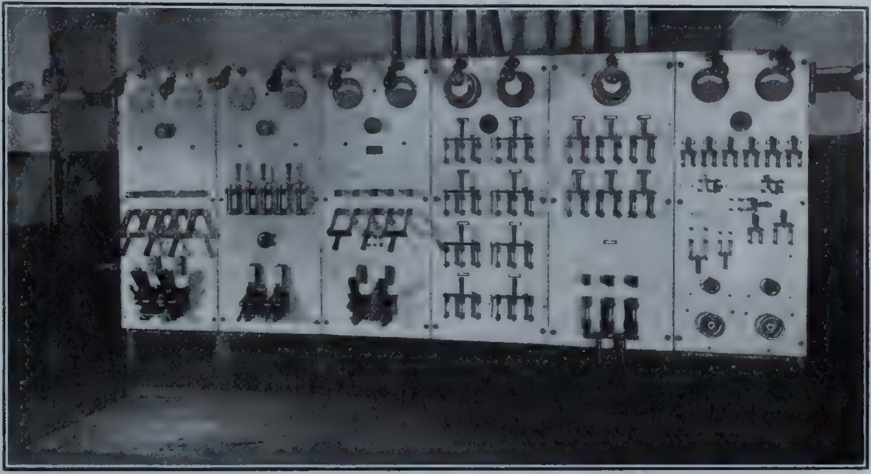
Heating and Ventilating.

The **Dunham** vacuum low pressure heating system is installed in the building. Exhaust steam from the generating units and pumps, etc., is circulated throughout at atmospheric pressure, while a vacuum varying from 4 to 12 in. is maintained in the return lines, depending upon the speed of the pump. Dunham thermastatic traps are fitted to all the radiators, steam mains, and at the bottom of the risers. These traps automatically respond to the different pressure conditions in the heating system, and operate the same on atmospheric pressure, or a few pounds pressure, or under vacuum conditions. The returns are collected in a receiver located near the vacuum pump, and are pumped to the feed water heater.



PUMP ROOM ARRANGEMENT.

Two separate fan systems are installed for ventilating certain sections of the building. One system comprises three motor-driven **Sheldon** fans, two being fresh-air fans, each having a capacity of 1,800 cub. ft. per minute, and driven by a 10-h.p. C.G.E. motor. The exhaust fan has a capacity of 20,000 cub. ft., and is driven by a 13-h.p. motor. One fresh-air fan ventilates the main ticket office on the ground floor and the second floor. The other fresh-air fan supplies air to the basement. The exhaust fan draws air from the main and the second floors.



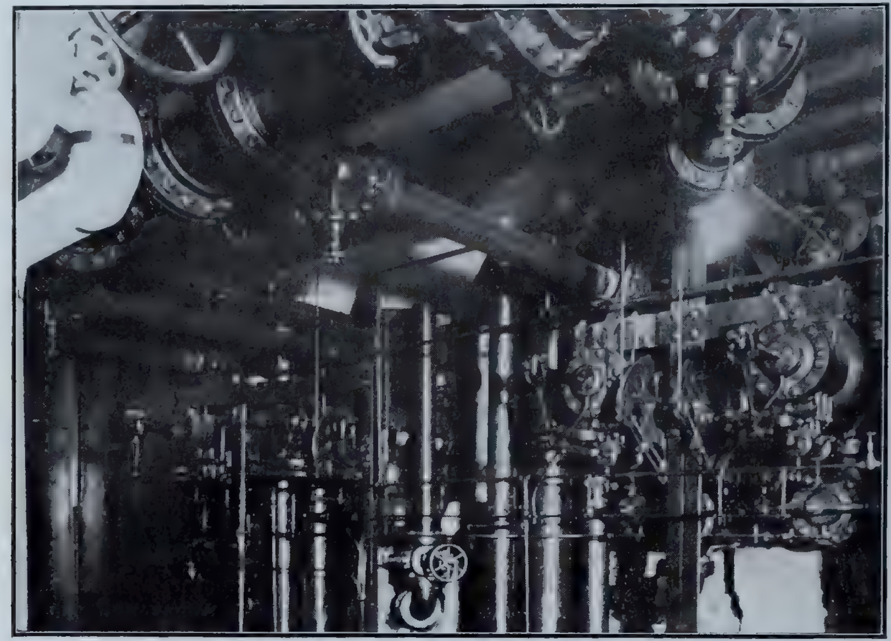
MAIN SWITCHBOARD.

The second fan system is located at the top of the building, and consists of two **Sheldon** exhaust fans, one having a capacity of 10,000 cub. ft. and the other 12,000 cub. ft. The former is driven by a 3-h.p. C.G.E. motor, and draws air from the telegraph rooms and the two top floors, while the latter fan draws air from all the lavatories throughout the building. This system also includes a fresh-air fan of **Sheldon** make, with a capacity of 15,000 cub. ft. and driven by a 7-h.p. C.G.E. motor. This fan supplies air to the two top floors.

In the discharge from each ventilating fan in basement there is installed a **Johnson** thermostat with relay valves, and **Johnson** diaphragm valves, controlling the steam supply to the individual sections of tempering coils, also by-pass damper beneath the tempering coils. These thermostats are set to any degree of temperature required in the sections ventilated by the fans. The tempering coils of fan serving the basement, although equipped with the control device, are not in service at normal times. Louvre dampers, approximately 20 sq. ft., are installed in the ducts leading to the fresh-air fans, and a damper is also installed in the duct leading to the exhaust fan. The louvre dampers are all automatically controlled by diaphragm motors.

The tempering coils of the fresh-air fan at the top of the building are equipped with a **Johnson** thermostat with relay and diaphragm valves. A by-pass damper is installed in the fresh-air intake of this fan, and is equipped with a diaphragm motor. Louvre dampers are installed in the discharge ducts from the two exhaust fans. These dampers are also equipped with diaphragm motors.

The louvre dampers are all controlled from pneumatic switches on a switchboard located in the engine-room, which is also equipped with a pressure gauge. The compressed air for operating the temperature control devices is supplied from a vertical Canadian Westinghouse steam-driven air pump located in the pump room. The automatic temperature control system was installed by the Johnson Temperature Regulating Co., Toronto.



HYDRAULIC ELEVATOR CONTROL VALVES.

There is steam service to the adjacent premises occupied by the Bowles Lunch Co. Exhaust steam is supplied for heating building, there being a total of 2,000 sq. ft. of heating surface, while live steam is supplied for such purposes as cooking, lavatories and barber shop. The amount of steam supplied in this way is measured by passing the returns through a "**Bundy**" return trap, which will hold a given amount of condensate. When full, the trap dumps and at the same time operates an indicator which shows the number of times the trap is emptied, thus making it an easy matter to calculate the amount of steam used. The returns from this source are delivered with the feed water to the boilers.

Fire Service.

Stand pipes are installed with hose connections on each floor. The **Underwriter** pump, already described, is connected to the stand pipes. In connection with the fire service is an alarm system. On each floor is a break-box connected with an annunciator and bell in the engine-room, the former indicating the floor from which the alarm has been sent in. This system was installed by the Neilson Electric Co., Philadelphia, Pa.

The Vacuum Cleaner System

A vacuum cleaner system has been installed throughout the building. In the pump-room is located the machine which was supplied by the American Rotary Valve Co., Chicago, Ill., through Geo. H. Tod, Toronto. It has a capacity of four sweepers and 285 cub. ft. of air per minute, and is capable of maintaining a vacuum of 12 in. It is of the reciprocating type, and is operated by a 15-h.p. **Jenny** motor. The machine can be reversed to pump air through the system to clean inaccessible places, such as behind radiators, and is in addition equipped with a mechanical self-cleaner.

Pneumatic Messenger Service.

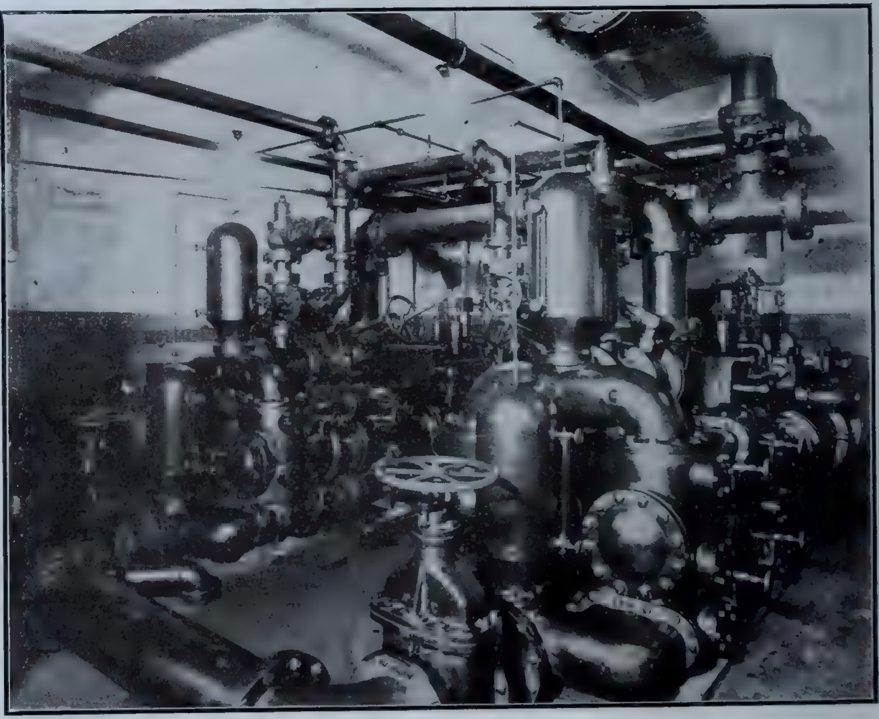
Between the telegraph department on the top of the building and the messenger department in the basement are a number of pneumatic tubes which are supplied with air from a blower located in the pump-room. The blower is of the positive rotary type driven by a 3-h.p. Sprague Electric Co. motor, and supplied by the Connersville Blower Co., Connersville, Ind. The blower is capable of delivering 3.3 cub. ft. of air per revolution and runs at 300 r.p.m.

Miscellaneous Features.

There are thirty-two watchmen's stations, each being connected electrically to an indicator in the engine-room, which is equipped with a recording chart. This system was installed by the Holtzer-Cabot Electric Co., Boston, Mass.

The electric clock system was installed by the Self-Winding Clock Co., New York. There are eleven clocks controlled by a master clock placed on the telegraph floor, and synchronized every hour. The clocks are self-winding and self-adjusting, these operations being performed electrically and controlled from a low tension circuit.

The consulting engineers were James McAlear & Co., of Chicago, the work being supervised by J. Melvin Thomas, of Toronto. The plumbing and heating contract was carried out by W. J. McGuire & Co., Toronto. The counter railings in the ticket office and the fire escape were supplied and installed by the Architectural Bronze and Ironworks of Canadian Allis-Chalmers, Ltd., Toronto, while the mail chutes were supplied by the Canadian Cutler Mail Chute Co., Montreal. The G. A. Fuller Co., Toronto, were the general contractors.



WORTHINGTON ELEVATOR PUMPS.

Boiler Inspection Service, Saskatchewan Province

By R. M. Blackburn *

In view of the diversity of regulations in the various provinces of the Dominion relative to steam boiler inspection and engineers' licenses, this article has a direct personal interest for readers of our journal. It goes to show that, in the realm of stationary steam engineering, Canada's Western provinces are not only away ahead of those in the East in the matter of boiler inspection regulations, but that higher standard service possibilities are brought within reach of the operator.

THE subject of boiler inspection occupies a large place among engineers both in Canada and the United States. Several provinces of the former and states of the latter have adopted compulsory inspection, while others have the matter under consideration. Although it is not intended in this article to present arguments in favor of compulsory boiler inspection, which at the present stage should scarcely be necessary, a brief account of the boiler inspection service in Saskatchewan will no doubt be of interest. The first act providing for the compulsory inspection of steam boilers in the Province of Saskatchewan, was passed by the Legislative Assembly in 1898, and a new act was passed in 1906, which subject to later amendments, is still in force. The acts have operated very successfully, and there have been very few serious accidents since the inspection service was inaugurated.

Efficiency of Boiler Inspection.

The efficiency of boiler inspection depends almost entirely on the capabilities of the individual inspectors, and it is of the highest importance that men appointed for this service should thoroughly understand their work and be able to command the respect of engineers and others with whom they come into contact. The Saskatchewan Act provides that no person shall be appointed an inspector unless he has had at least four years' experience as a practical machinist or boiler maker, is the holder of a first class engineer's certificate, and has also passed a special examination on the construction, maintenance, etc., of steam boilers. It may be mentioned here that a high standard of qualification is required to obtain a first class engineer's certificate in Saskatchewan. Candidates for this class of certificate are required to possess a thorough knowledge, both theoretical and practical, of the operation of steam boilers and engines and in consequence, very few of these certificates have been granted.

Province Imports Boilers.

Few boilers are built in Saskatchewan, nearly all of them being manufactured elsewhere, and shipped into the province. During the last few years an average of considerably over 500 new boilers per annum have been brought in, about 40 per cent. being manufactured in Eastern Canada, the remainder coming principally from the United States.

Owing to the very diverse standards of construction adopted by the several manufacturers it was very soon realized that an adequate system of boiler inspection should commence with the supervision of the design and construction of boilers shipped into the province and that a minimum permissible standard of construction and workmanship should be adopted. After some correspondence with neighboring provinces a conference was held at Regina in December, 1909, which was attended by representatives of the Governments of British Columbia, Alberta, Saskatchewan, Manitoba and Ontario. At this conference regulations were drawn up governing the construction of steam boilers and providing for the examinations and registration of designs. These regulations were at once adopted by the Provinces of Alberta and Saskatchewan and have more recently been adopted by the Province of Ontario. Regulations governing the construction of steam boilers, have been in force in British Columbia since 1902. These regulations are somewhat similar, but not identical, with the regulations drawn up at the Regina conference.

Registration of Manufacturers' Designs.

An important feature of the new regulations was the compulsory registration of manufacturers' designs. This was at first somewhat resented by a few manufacturers. It has, however, been found to operate well in practice and to have advantages over the methods followed by some authorities. In the first place, the rule brings manufacturers into closer touch with the boiler inspection department on questions of design, and avoids any misunderstanding which, in view of the many different types of boilers in use, is always possible even with the most carefully-worded regulations.

When a design has been approved and registered the manufacturer can build any number of boilers to that design, and, provided the workmanship is up to the standard, he can be sure that the boiler will meet the requirements of the department, and that the boiler will be allowed to carry the registered steam pressure. He is thus in a position to guarantee to the purchaser that his boiler will pass inspection for a certain pressure per square inch. Any novelties in construction or departures from standard practice can also be submitted to the department and discussed before being adopted.

In Massachusetts and other States the boiler inspection department does not make a practice of approving detail drawings of boilers, and the interpretation of the rules is left to the manufacturer who cannot be sure, especially in the case of a new design of boiler, that the boiler will pass inspection until it is actually built. It is obvious that an arrangement of this kind would not be satisfactory where boilers for use in the province are manufactured over so wide an area, and are frequently shipped long distances to the purchaser.

Inspection Staff.

Up to the present about 450 designs of boilers and over 300 designs of steam fittings have been approved by the department. A fee of $10 is made for the registration of each design of steam boilers, and a fee of $3 for the registration of each design of fittings, etc.

There are at present thirteen district boiler inspectors, together with a chief inspector, whose headquarters is at Regina.

Each district inspector is allotted a separate district, and is required by the Steam Boilers Act to inspect each boiler in his district at least once in each year. In the more sparsely-settled districts it has not been found practicable to entirely cover the entire district each year, but as far as possible this is done. Each boiler is numbered and a record giving full particulars covering its condition at the time of inspection and particulars of repairs ordered (if any) is transmitted by the inspector to the head office and filed. A history is thus kept of each boiler in the province. The number of boiler inspections made during last year was 2,818, and repairs were ordered on 536 boilers. A brief summary of the defects noted and repairs ordered during the past year will be of interest.

---

*Chief Inspector of Steam Boilers, Regina, Sask.

Defects Noted and Repairs Ordered.

Bulged and warped crown sheet to be set back or straightened, 60.

New stays ordered in firebox sides or crown sheets, 41.

New head-to-head stays required, 16.

Belly stays to be put in flue sheets, 19.

Leakages at seam to be caulked, 11.

Bulged side sheets to be set back or stayed, 5.

Leaky flues, 20.

New flues ordered to be put in, 20.

Boilers to be entirely re-flued, 23.

Leakages at stays to be caulked, 10.

Flue sheets bagged, 13.

New mud ring required, 1.

Bags in shells in return tubular boilers, 9.

New courses ordered, 2.

Girth seams, new rivets required, 4.

Plates to be patched, 7.

Leakage at bracket bolts of traction boilers, 15.

Repairs to brickwork setting and suspension, 10.

New steam gauges ordered, 58.

New safety valves ordered, 55.

New blow-off valves ordered, 43.

Fusible plugs to be renewed, 44.

Injectors, check valves, feed pipes, etc., to be renewed or repaired, 46.

Water glass mountings, try cocks, etc., to be renewed, 24.

Syphons to be provided for steam gauges, 9.

Alterations required to water column or connections, 8.

New stop valves required, 10.

Blow-off pipes to be altered, 8.

Defective feed pumps, 5.

Provide additional means of feeding boilers, 8.

Boilers ordered to be cleaned or scaled before further use, 5.

Boilers condemned as unfit for further use, 3.

Sundry repairs, 66.

Observations on Boiler Defects.

In the above list the number of warped and bulged crown sheets is noticeable. This is due in great measure to the bad feed water used in many parts of the province, especially for agricultural engines. Much of the feed water is alkaline, and contains a great deal of mud and deposit, which, settling in the crown sheet when the boiler is at rest, causes overheating when the boiler is fired up again. That the warping of the crown sheet is not caused to any great extent by neglect in washing out the boiler is shown by the comparatively few cases of bulging of the sides of the firebox near the bottom of the water leg. The regulations now require all new traction boilers to have arched crown sheets. This to a considerable extent prevents the mud lying on these, but a large number of the older traction boilers in the province have flat crowns, and the trouble usually occurs with them. The alkaline water is also severe on flues and stays, causing leakages at the joints.

Steam gauges are frequently damaged by frost, through not being properly drained when not in use. The department requires all traction boilers to be provided with double tube gauges. These are more readily drained, and the pointer is also more steady when the tractor is in motion than in the case of single tube gauges. The regulations also require that each boiler shall have two separate means of feeding water.

Want of proper care when traction boilers are out of use frequently causes boilers to deteriorate much more rapidly than they should. After the threshing season, the boiler is generally left exposed to the weather; ashes and soot are left lying in the fire-box and smoke-box, and the engine is sometimes left just as it was when the threshing was finished until next season. The ashes and soot attract moisture, rain finds its way down the smoke stack and keeps the soot and ashes in the smoke-box wet. The consequence is rapid corrosion of the front tube plate, fire-box and smoke-box.

The importance of removing all ashes and soot and thoroughly cleaning out the boiler at the end of the season is fairly well understood by most engineers, but is not sufficiently appreciated in some cases by the owners of traction engines, who are sometimes unwilling to retain the services of the engineer a moment longer than they can help after threshing is over.

There are over 6,000 boilers in the province; these boilers are at present being re-numbered, and full particulars of each are being taken and filed at the head office. This work is not yet completed, although, up to the present, records of over 4,500 boilers have been taken and placed on file for ready reference.

Engineers' Licenses.

All engineers in the province are required to hold licenses from the steam boilers branch of the Department of Public Works. These licenses are divided into five grades, of which the first, second and third-class certificates, together with traction engineers' final certificates, are good for life. The examination for these certificates is a written one, and the standard of qualification is fairly high, especially for a first-class certificate. Provisional certificates authorizing the holder to operate boilers not exceeding 40-h.p. for a period of one year from date of issue are granted to applicants having the necessary experience upon passing an oral examination before a boiler inspector. These certificates can be renewed on expiration, or the holder may, if he desires, take a written examination for a final certificate.

Examinations for all grades of certificates except for first-class certificates are held during the winter months at all principal railway points on advertised dates, and examinations can also be taken on the first Monday in each month at each district inspector's headquarters. Examinations for first-class engineers' certificates can only be taken at Regina.

The number of certificates issued during last year was as follows:

Provisional certificates...........	3,858
Third-class engineers' certificates..	517
Second-class " " ..	68
First-class " " ..	19

The traction engineer's final certificate is a new grade of certificate authorized by the last session of the Legislature, and is intended more especially to meet the requirements of threshermen and operators of agricultural engines.

Any certificates may be suspended or canceled for gross carelessness, inefficiency, intemperance while in charge of a steam boiler or a serious breach of the Steam Boilers Act. Few cases, however, occur of this kind, as considerable care is taken in granting permanent certificates.

By a recent amendment the Steam Boilers Act has been extended to cover low-pressure heating boilers in apartment houses, office blocks, hotels and public buildings, and when these boilers exceed 40-h.p., the operator is now required to hold a fireman's certificate.

The efficiency of the boiler inspection is shown by the few accidents which occur. With the exception of warped and bulged crown sheets and shells, none of which were very serious, no accidents occurred during the past year. The only calamity reported was an accident caused by a man stepping through a hole in a sawmill floor near the engine fly wheel, where a plank had been removed a few days before in order to take off the wheel and had not been replaced. The unfortunate man fell on the belt and was taken around the wheel and instantly killed.

◆

Finding Compressed Air Leaks. — When steam escapes you can generally see or hear it, and when there is a leak in an ammonia pipe line that also is immediately evident, but a leak in a compressor air line entailing an appreciable loss may go for a long time unnoticed; not that it is more difficult to make the air line tight, and to keep it tight, than the others. An Illinois manufacturer at regular intervals puts essence of peppermint into the air system, and then has all the pipes inspected for leaks. If the smallest amount of air escapes anywhere it is revealed by the odor.—Ex.

PROBLEM OF COAL STORAGE.

THE problem of coal storage is an impotant one to every power house engineer. In order to safeguard the continuity of power supply when there is a shortage of coal due to strikes or other causes, a reserve supply of fuel must be kept. It is, however, by no means an easy matter to store coal in a satisfactoy manner, because even if means are taken to avoid the obvious forms of trouble such as spontaneous combustion, there is always—when coal is exposed to air — a slow oxidation which tends to deteriorate the calorific value of the fuel. A good deal of attention has been paid to this matter within recent times, and one or two notes on the subject may be of interest.

U.S. Bureau of Mines Investigation.

The United States Bureau of Mines recently investigated the deterioration of various kinds of coal under storage, and it was found that, while several coals evolved methane in large volumes, especially in the early period after mining the coal, the gas evolved in one year from this cause means a maximum loss in calorific value of 0.16 per cent., this loss covering a period of one year from the time the coal was mined. The Navy Department tests show a loss of less than 1 per cent. in a year on New River coal weathering in the open; and Pocahontas coal in a 120-ton pile on the Isthmus of Panama lost less than 0.4 per cent. during one year's outdoor weathering. Pittsburgh gas coal suffered no loss whatever during six months' outdoor weathering. Wyoming coal, however, lost 5.3 per cent. during two years and nine months, 3.5 per cent. of which was lost in the first three months. For a distance of from 12 to 18 in. from the surface there was bad slackening and crumbling of the lumps. Illinois coal as tested by Prof. Parr, of the University of Illinois, lost 1 to 3 per cent. in a year with slackening and crumbling.

The average value therefore appears to be a loss of 1 to 3 per cent. of heating value in one year, a large percentage of this loss occurring within from three to six months after the coal has been placed in storage. Mr. Perry Barker, in a paper before the American Society of Mechanical Engineers, says that some results of tests on German gas coals have been given which state that these fuels have lost an average of 1.7 per cent. of heating value per week, but on the basis of the American tests it is apparent that the loss in heating value is not the most serious consideration in the question of coal storage.

Spontaneous Combustion Danger.

The danger which is to be most carefully avoided in connection with coal storage is the more rapid form of oxidation known as spontaneous combustion. Mr. Barker names the causes of spontaneous combustion as the escape of inflammable gases from fresh coal surfaces, the absorption of oxygen from the air with the production of heating, the presence of fine coal which brings large surfaces into contact with the air and so accelerates the oxidation of the whole mass, the presence of an excessive amount of moisture (especially if the coal under storage becomes alternately wet and dry), and in some cases the presence of external causes of heating even if these are very moderate in amount.

As regards the escape of gases, he states that the results of experiments in freshly mined coal show that the loss of gases is about equal to the volume of coal, and the heating value of such gases amounts to 0.1 or 0.2 of the heating value of the coal. The point about this is not the actual calorific value which is lost, but the danger of explosion attending on the escape of such inflammable gases; while the evolution of heat accompanying oxidation is one of the great causes of danger of spontaneous combustion in coal piles. Heat from steam pipes, boiler and walls also tend to the ignition of the mass.

Avoiding Spontaneous Combustion.

Various authorities have advocated means of avoiding spontaneous combustion. Summarizing various recommendations, it may be said that safety is promoted by observing the following precautions. Combustible gases (that is to say, gases which are likely to separate out freely) should be eliminated before storage; in other words, freshly mined coal—particularly if it is gassy—is not safe for storage, and about six weeks' seasoning should be allowed after mining before storage. The storage piles should not be over 10 to 12 ft. deep, and should be so disposed that any point in the interior will not be over 10 feet from the air-cooled surface. If possible, lump coal only should be stored, the removal of fine coal being effected by screening. Dust should be kept out as much as possible.

The method of placing the coal in storage should be such that it is not broken up during handling. If a mixture of lump and fine coal is stored, the various sizes should be well mixed together and evenly distributed so that the formation of air passages is avoided. These very often occur if the storage pile is so formed that large lumps roll down from the peak and form air passages at the bottom. It is not wise to attempt ventilation by pipes; and care should be taken to see that there is no infiltration of air through brickwork, timber or porous foundations, such as coarse cinder. It is a useful precaution to rehandle and screen the coal after every two months.

There is great danger of gas explosion as well as spontaneous combustion if powdered coal is stored. Fine coal, if required, should be pulverized immediately before use in the furnace and at the rate required at the time. Weather conditions should be guarded gainst where the coal is subject to wetting and drying. For example, a bad storage would be one in which the rain can fall on the pile and be subsequently dried off by the sun or the warmth from steam pipes. External sources of heat, even moderate in degree, should be carefully kept away from the coal pile.

Submerged Storage.

Heating extending to spontaneous combustion, it is maintained, can be eliminated by submerged storage. It is stated that in cases where coal has been stored under water in concrete tanks of considerable capacity, the practically negligible loss in calorific value thus obtained considerably more than counterbalances the increased amount of moisture in the coal as fired to the boiler furnace, and such submerged storage renders spontaneous combustion impossible. Moreover, the result is obtained regardless of the size of the coal stored. A large Chicago manufacturing firm employing this method has found that with Illinois coal ranging from dust up to about 1¼-inch lumps, the method works satisfactorily. The fuel, after being loaded out for storage, is allowed to drain for a few hours before passing to the chain-grate stokers with which the boiler furnaces are fed.

It is stated that the cost of handling coal in a scheme of this sort should not be more, and may be distinctly less, than when it is piled upon the ground in the open air. Mr. Barker refers to a method which has been recently adopted in order to reduce the amount of contained moisture in coal storage in permanent contact with water. This is by only partially submerging the coal; and it is stated that the exposed portion of the coal pile absorbs a sufficiently high percentage of moisture through capillary action to prevent any danger of serious oxidation.

The above notes give only in brief outline the general features of a problem which is of very great interest to all power-house engineers, but the suggestions may form a sufficient starting point for investigations to be carried out with the object of reducing the large margin of loss and danger which at the present time exists in many coal storage schemes.—Engineering Review.

Results of Neglected Leakage from Boiler Joints, Et

Through the courtesy of the Vulcan Boiler & General Insurance Co., Ltd., Manchester, England, we are enabled to lay before our readers a record of Continental Europe practice and experience relative to defects met with by the Steam Boiler Inspection Association of Brussels, Belgium. The descriptive matter and illustrations go into minute detail, and are non-technical, making the educative feature interesting and easy of appropriation.

FURTHER and diversified examples of the effects produced on steam boiler vitals through leakage and consequent corrosion are here featured, and, as pointed out in the introductory note of a similar article in our May issue, close attention to the cure of leaks, however caused and seemingly unimportant, is incumbent on all interested or engaged in steam boiler safety operation.

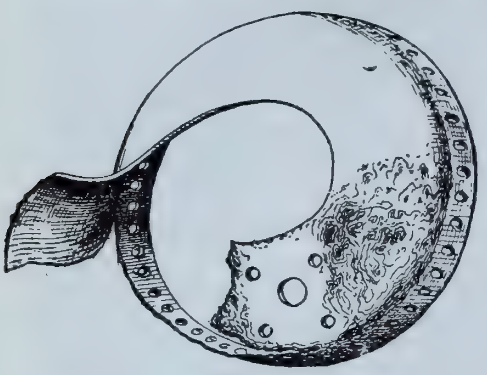


FIG. 12.

Corrosion Round Joints and Parts Not Covered with Brickwork.

Fig. 12 shows the front end plate of a boiler superheater. Owing to leakage at the joint of the manhole, severe corrosion of the lower part of this end plate has occurred. This corrosion is most extensive at the lower curvature towards the left at the part where the brickwork tends to hold the moisture. The thickness originally of 11.5 m.m. is, over a space of 400 m.m., reduced to nothing.

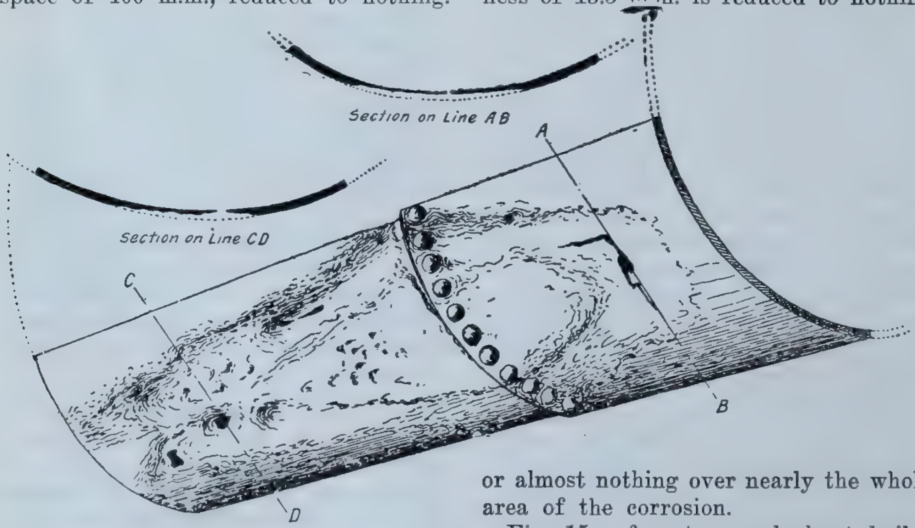

FIG. 14.

The end plate has given way along the curvature, and this first rupture has extended as far as the manhole across a very severely corroded part in which the thickness varied from nothing to 11.5 m.m.

Corrosion at the Point of Contact with Brickwork.

Fig. 13 shows the base of the neck connecting the steam receiver of a multitubular boiler with the nest of tubes. —This part is covered with brickwork. Persistent leakages at the expanded part of the tubes have caused severe corrosion. The original thickness was from 6 to 7 m.m. It has been reduced to nothing on the whole circumference and for a height of 20 to 70 m.m.

Fig. 14 represents the bottom of a mud-drum of a multitubular boiler. The lower part was in contact with brickwork, dust, etc. Owing to a leak at the circular seam severe corrosion has occurred over a space varying from 300 to 600 m.m. This corrosion has only attacked the part where contact with external substances has retained moisture. It is almost uniform. The original thickness of 13.5 m.m. is reduced to nothing or almost nothing over nearly the whole area of the corrosion.

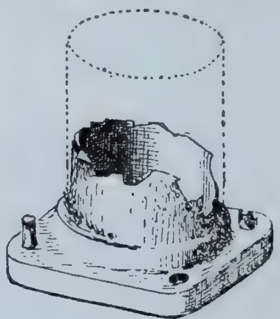

FIG. 13.

Fig. 15 refers to an elephant boiler with two drums. Corrosion arose at the bottom of the back end shell ring of one of the drums owing to leakage at the manhole joint. This part being covered by brickwork was always in a damp condition. The corrosion extended over a length of 350 m.m., with a maximum breadth of 120 m.m. The thickness is reduced to nothing at the lap, the breadth of which is reduced. The seam has been least attacked, there being a remaining thickness of about 5 m.m. In front of this the corrosion increases, and at one point a hole has been formed, The rivets are headless. The original thickness of the plate was 9.5 m.m.

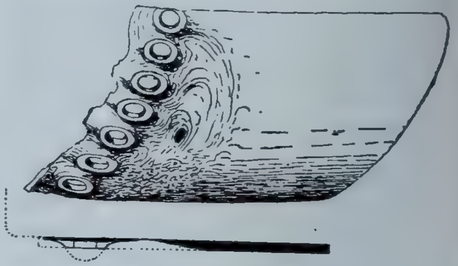

FIG. 15.

Corrosion of Parts Fired by Gases.

Fig. 16 shows a tube in the lower row of a multitubular boiler set over a puddling furnace. The tubes had an original thickness of 4 m.m. Corrosion arising from the sulphuric acid contained in the gases has affected them in a manner almost uniform. At the place of fracture, the tube which failed has a thickness varying from 0 to 2 m.m.

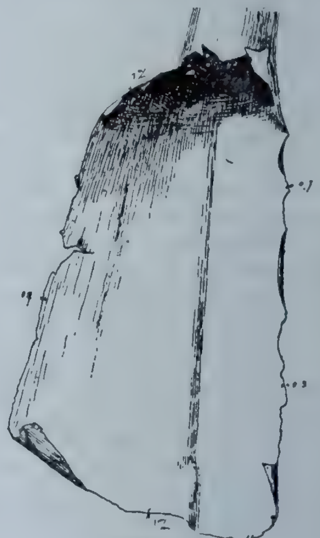

FIG. 16.

Fig. 17 represents a piece of a flue tube of an elephant boiler with two drums and flue tubes, fired with coke dust. The plate indicates an appearance of general wear and tear which have reduced its thickness from 3 to 4 m.m. At the center of the piece there is a blister, of which the exterior side has not been attacked so severely by the corrosion. It is probable that by reason of the non-adherence of the coke dust, the exterior side has generally been in a hotter condition and was able in consequence to better resist the corrosion.

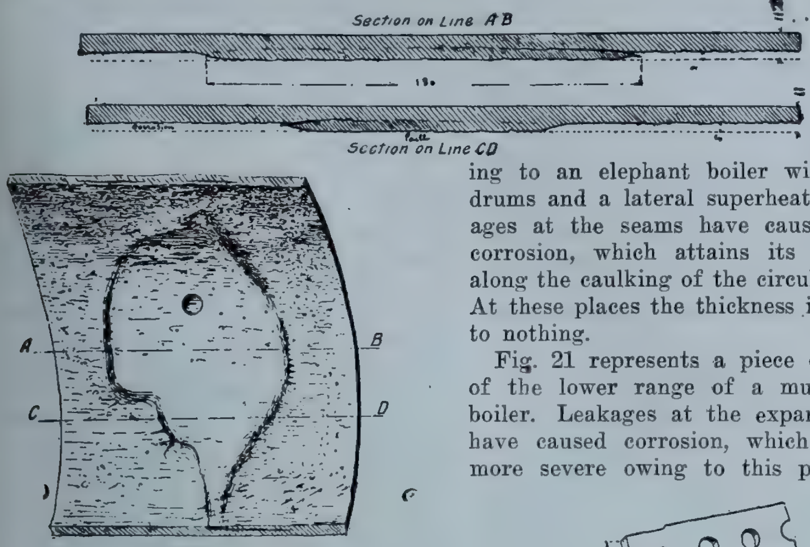

FIG. 17.

Corrosion of Parts in Contact with the Fire.

Fig. 18 refers to a boiler with two superheaters set to work in 1891. A piece of the superheater plate (original thickness 9 m.m.) is the part affected. Leakages at the overlap of the circular seam have caused severe corrosion, which extends over a space of 450 m.m. in length with a breadth at the overlapping part of 300 m.m. A little below this, the thickness is reduced to nothing at one point. The corrosion extends almost into the seam itself, where it is, however, of little importance. The heads of the rivets are slightly affected. The corrosion developed in four years.

Fig. 19 belongs to a boiler with superheater, the illustration showing a piece of the superheater plate (original thickness 7.5 m.m.). Leakages at the overlap of the plates have produced a corroded groove, which extends along the circular seam. Its breadth is 70 m.m. The corrosion is greatest near the overlap, where at one point the plate is holed. Commencing from this point it decreases rapidly.

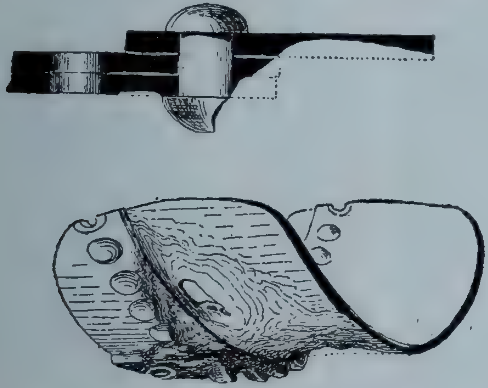

FIG. 18.

Fig. 20 shows a piece of the high part of one of the circular seams of the superheater, thickness 11 m.m., belonging to an elephant boiler with three drums and a lateral superheater. Leakages at the seams have caused severe corrosion, which attains its maximum along the caulking of the circular seams. At these places the thickness is reduced to nothing.

Fig. 21 represents a piece of a tube of the lower range of a multitubular boiler. Leakages at the expanded part have caused corrosion, which was the more severe owing to this part being generally covered with soot. A piece of the tube has been displaced by the pressure.

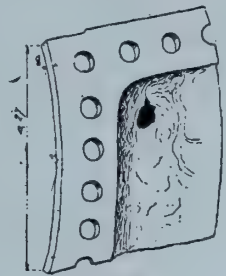

FIG. 19.

* * *

HARD WATER FOR BOILER FEED.

PROBABLY the greatest loss caused by the average hard water is due to the formation of scale on the heating surfaces of the boiler. Scale, being a nonconductor of heat, tends to insulate the heating surfaces of the boiler from the water within, so that to evaporate the same amount of water a greater amount of fuel must be used when the surfaces are scaled than when they are clean. As the amount of this loss depends directly upon the thickness and composition of the scale, the amount of heating surface covered, the type of boiler and the operating conditions, it is impossible to state definitely what the loss would be in any individual case.

Fuel Consumption and Scale.

There have been a great many purely scientific experiments made, the results of which demonstrate thoroughly that an excess amount of fuel is necessary to produce results on scaled boilers. In one case of a locomotive where the heating surfaces were covered with scale ranging from 1-32 to 3-64 in. in thickness, it was found that the locomotive would evaporate 12.6 per cent. more water after cleaning than when the tubes were scaled, the net increase in fuel consumption in this boiler being 9.55 per cent. Another series of tests on scaled boiler tubes taken from different boilers showed that the amount of fuel required to drive the same amount of heat through the tubes varied from 5.96 to 15.75 per cent., depending upon the thickness of scale. The average fuel loss in boilers using hard water is anywhere from 10 to 50 per cent., and this occurs not only in the boilers, but in enclosed heaters and economizers as well. In addition to the cost of this waste fuel, the cost of handling the coal and the ashes resulting from it must also be considered.

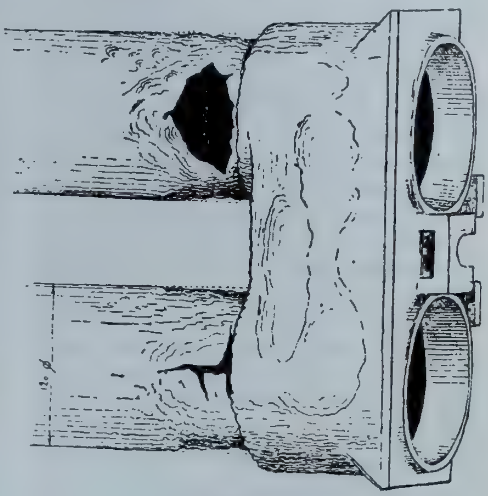

FIG. 21.

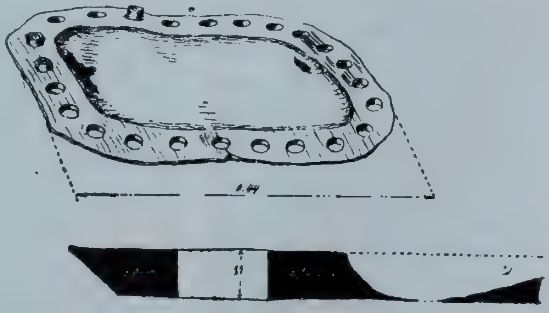

FIG. 20.

Decrease in Efficiency Caused by Scale.

In a number of cases the loss of fuel is not as important as the loss of efficiency. The insulating properties of the scale lower the efficiency of the boilers, at it is impossible to force as much heat through a scaled tube or sheet as through a clean one. This lowering of efficiency frequently reduces the actual capacity below the demand, so that additional equipment is required to carry the load. If this has to be installed there is another charge which must be placed directly against the effect of hard water.

While stokers or other apparatus are sometimes installed to overcome this loss in efficiency, at the same time they have a tendency to decrease the percentage of efficiency, as the additional evaporation causes more scale to be deposited with a further reduction in the actual efficiency. The presence of scale in water tube boilers decreases the available heating surface by building up inside the tube and decreasing the area. The general practice with scaled boilers is to put them out of service and remove the scale by mechanical cleaners, and the cost of this work, together with the investment on the tools used, must also be taken into consideration.

Foaming and priming of boilers is often caused by the presence of certain scale-forming ingredients in combination with organic or suspended matter. A foaming boiler by mechanically carrying water from the boiler greatly decreases the steaming capacity, and, in addition, there is the danger of getting water into the engine cylinders, which tends to reduce the effect of lubrication and cut both the cylinder and the pistons.

Fuel Required to Recommission a Boiler.

After a boiler is cleaned, the amount of fuel required to place it in service is directly chargeable against scale, as the boiler was in operating condition at service pressure when it was taken off for cleaning. The amount of coal required to accomplish this is approximately 2,000 lb. per 100 boiler h.p., and its cost can be estimated directly by the number of B.t.u. which are required to raise the temperature of the water in the boiler from 200 deg. F. to 338 deg., which corresponds to a guage pressure of 100 lb. As a 100 h.p. boiler holds approximately 190 cubic feet of water, it will require 12,065,000 B.t.u. to put the boiler into service at 100 lb. pressure, which will theoretically require 1,150 lb. of coal, containing 10,500 B.t.u. per lb., or 1,533 lb. if 75 per cent. boiler efficiency is maintained. As a matter of fact, the amount of coal required will be approximately 2,000 lb. to take care of the amount of heat absorbed by the furnace and the masonry work.

Boiler Accidents a Result of Scale.

Scale and corrosion are responsible for a large number of boiler repairs, many of which are caused by burnt or ruptured sheets or tubes that have become overheated through the insulating effect of the scale. Out of a total of 136,682 boilers inspected in 1909 by the Hartford Steam Boiler Inspection and Insurance Compaany, 8,165 were reported as defective through burnt or fractured plates, 18,607 defective through leaky seams and tubes, and 17,274 defective through internal corrosion. In addition, 106,141 boilers were reported as defective and 6,755 as dangerous, through reasons directly traceable to the presence of scale or corrosion.—From a paper by K. W. Bartlett, inventor of the Bartlett-Graver water softener, East Chicago, Ind.

VENTILATING THE COAL PILE.

A simple device to prevent spontaneous combustion where bituminous coal is stored in large piles was adopted recently by the Swineheart Tire & Rubber Co., Akron, Ohio. At 12 feet intervals throughout an 800 ton pile of coal vertical vent ducts were placed. These ducts, consisting of square boxes made of 10 in. boards in which 1 in. holes were bored on 6 in. centers, were placed upright on the site used for coal storage, and the fuel was dumped about them. The function of the pipes is to carry off the heat and gases formed in the interior of the stored coal, thus preventing undue rise in temperature and formation of gas pockets.

H. L. Houk, purchasing agent for the company, says that their experience with run-of-mine coal has shown that spontaneous combustion need not be feared with vent pipes placed vertically on 12 feet centers. Where slack coal is to be stored, he believes that horizontal ducts leading to the vertical risers should be installed.

CAST IRON IN BOILER VALVES.

From the Board of Trade report of the explosion from a boiler stop valve chest at Pinkston Tramway Power Station, Glasgow, on November 10th, 1913, it appears the explosion was due to the long-continued action of superheated steam on the cast iron, causing disintegration and deterioration of the material of the valve chest, and it is added that a number of manufacturers have entirely ceased to use cast iron when superheat is specified, not only in land installations, but also in connection with marine work, as they do not consider it reliable. Power stations in Glasgow are now to be entirely equipped with steel mountings on boilers and steam pipes. It would seem, indeed, if superheating becomes common, or much higher boiler pressures are to be used in the future, that cast iron must be barred for boiler stop-valves and steam pipe ranges, either as junction pieces or expansion glands.

CONCRETE SMOKESTACKS.

Numerous practical trials, says a writer in The Power User, have shown that concrete and reinforced concrete are quite suitable for the construction of smokestacks.

The design of concrete stacks as regards internal diameter and height proceeds as for masonry stacks. To withstand gas temperatures exceeding 570 degs. F. a refractory lining should be fitted to the parts concerned. Iron and concrete have practically the same coefficient of thermal expansion, but very different heat conductivities, and unless the iron be deeply embedded, it is likely to become hotter or cooler than the concrete, and hence to break its bond with the latter.

As regards air leakage and thermal losses, concrete is at least equal to masonry. Boiler gases do not attack concrete appreciably, but in chemical works it is necessary to distinguish between acid fumes forming soluble or insoluble calcium salts. Hydrochloric, acetic, and nitric acids form soluble calcium salts, and are most injurious; but sulphuric and fluoric acids form insoluble salts, hence their action is much less injurious, and can be practically eliminated by a light lining or by coating with tar.

Concrete smokestacks originated in the United States, but a number are now in use in Europe. The monolithic type, in which the finished stack forms a continuous one-piece structure, is often built as a simple cylinder for the sake of simplicity. Recently, however, monolithic stacks have been built to a more pleasing form, and one utilizing materials more efficiently. As the cement takes some time to set, the time occupied in and the wages charged for building are higher than for a masonry stack.

The relative accessibility of raw materials for concrete, and of formed or radial bricks for masonry stacks, frequently determines which construction is ultimately the cheaper. Generally large reinforced concrete stacks are about 20 per cent. cheaper than the equivalent masonry structure, and the weight of the former is about 40 per cent. that of a masonry stack of equal height and internal diameter—an important consideration where the subsoil is yielding in nature.

The vertical reinforcing members of a monolithic reinforced concrete stack are generally tied to a cast-iron head ring, but the metal skeleton thus completed should not be relied upon entirely as a lightning conductor. An external copper conductor should also be provided.

INSPECTION OF GOVERNMENT COAL PURCHASES.

THE inspection of coal purchased for the U. S. government is conducted from the headquarters of the bureau in Washington, where the engineer in charge of the inspection service is stationed and the laboratory for analyzing samples of deliveries is situated.

The work done includes collecting, analyzing and testing of samples representing deliveries of coal purchased under Government contracts providing for purchase on a specification basis, in order to ascertain whether the coal represented by the samples conforms to the stipulations of the contracts. On such contracts the bidders guarantee the quality of the coal they offer, and the quality guaranteed by the successful bidder becomes the standard of his contract.

A large part of the coal used by the Government for its power plants, public buildings, and naval stations is purchased under contracts that specify the ash and the moisture content, the heating values, the limits of the content of volatile matter, and the sulphur content. The analysis of samples of deliveries determines whether the quality of the coal is up to the standards guaranteed by the contractor. If it is not, the price to be paid is decreased in proportion to the lower value of the coal; if the coal is of higher quality, the price is proportionately increased.

Definite Scheme of Procedure.

In the collection of samples, a definite scheme of procedure is observed. By following the instructions of the Bureau of Mines, and by observing every practicable precaution, the collection of samples fairly representing the coal delivered is insured. The gross samples taken are reduced by successive crushings, mixings, and partings to samples that weigh about three pounds. These are sent by mail to the laboratory at Washington.

The larger part of the coal now bought by the Government is purchased under the general technical supervision of the Bureau of Mines. The cost of purchases under specifications prepared by the bureau for the use of the Government now aggregates approximately $4,500,000 per annum, and the additional fuel bought under the general advice of the bureau now aggregates in purchase cost some $3,000,000 per annum more, making a total value not less than $7,500,000.

Benefits Derived.

The benefits to the Government from this work of the bureau have been both general and special. In the case of the purchase of coal by the Isthmian Canal Commission for the Panama Railroad during the fiscal year 1910 and 1911, the money actually saved by the Government was nearly $75,000, and the real saving was probably several times these figures, because the method of purchase insured deliveries of coal of a higher grade than would otherwise have been obtained. Other examples might be mentioned, among them the savings effected by the Quartermaster Corps, War Department, which amounted to $27,500 during the fiscal year 1912.

Some benefits to the general public resulting from this work for the Government may be indicated by the fact that more than fifty of the larger cities, a number of states, and a large number of private corporations and business concerns in different parts of the country have followed the general plans adopted by the Government for the purchase of its coal. The analyses of coals from the different coal fields of the country, analyses that have been made in testing these coals for the use of the Government, have been of great service to engineers in charge of power plants and to manufacturing industries throughout the country, enabling users of fuel to determine in advance the character of the coals available for local or special use. The specification method of purchase protects the Government against the delivery of poorer coal than that guaranteed by the contractor and incites dealers to prepare the coal more carefully.

In the case of coal for use on naval vessels, at the request of the Navy Department the mining and shipping facilities of mines from which purchase is proposed are carefully examined by the engineers of the Bureau of Mines, and the samples collected from each mine are analyzed at the Pittsburgh laboratory; in this way a standard of high-grade coal, low in ash and volatile matter, is fixed, and must be maintained in subsequent shipments. Occasionally samples are collected as the coal is being loaded on ships, and if the results show that the coal as loaded is not up to the standard, the contractor is promptly notified that the quality of his shipment must comply strictly with the contract specifications, and on his failure to ship coal of specified quality his contract is annulled. Coal purchased under such specifications and used on naval vessels amounts in round numbers to 700,000 tons a year.

The steaming tests that have been conducted and the advice given by the bureau's engineers are resulting in further economies to the Government. For instance, by a change in the kind of coal used, one Government boiler plant is spending between $4,000 and $5,000 a year less than formerly for fuel, while another Government plant reduced its annual expense for fuel about $15,000. Other examples might be mentioned.

LOW PRESSURE BOILER EXPLOSIONS.

MANY steam users are under the impression that, when boilers or vessels to which steam is admitted for heating and boiling purposes are worked at low pressure, failure cannot produce serious results, though experience often shows this assumption to be untrue. In the early days of steam many terrible boiler explosions occurred, although boilers were then of a primitive type, and pressures used only a few pounds per sq. inch, which is insignificant as compared with modern practice. In the event, however, of the sudden rupture of a large boiler, even when working at low pressure, the amount of energy liberated is capable of doing great damage.

In the May issue of the Vulcan is an illustration taken from the Illustrated London News for December 27th, 1845, showing the havoc wrought by the bursting of a wagon boiler at a cotton mill at Bolton. The boiler was of a type which was incapable of resisting a high pressure, and though the actual working load is not stated in the brief account of the disaster, it seldom exceeded 12 lb. to 15 lb. on the inch. All the same, it sufficed, as the illustration shows, suddenly to convert a large part of a four-storied mill into a heap of ruins and kill ten workpeople, while nine others were more or less seriously injured.

◆

Steam Boilers in Central Stations.—In a paper on "Steam Boiler Operation in Central Stations," Mr. J. W. Jackson says:—"The selection of fire-bricks is one that naturally requires very careful attention. The particular make of fire-brick to be used depends not altogether upon the quality of the brick, but to a great extent upon its character. Some fire-bricks with great reputations run to slag very quickly indeed, while, again, other fire-bricks practically unknown do excellent work with the same coal. There is, of course, no great wonder at this when it is remembered that the sulphur content of coal varies very considerably, while, again, some coals contain a fairly considerable amount of impurity, such as fire-clay. This fluxes some makes of bricks very badly, and, on examining the furnace after quite a short run, it will be found that the molten fire-brick or slag has run down the underside of the furnace arch, cutting quite deeply into the fire-brick and practically making rivers running down the side walls and on to the grates, with the result that the fires quickly get into a very bad condition, and need to be cleaned by means of a long slice as frequently as once per hour."

SINCERITY ADVERTISING.

FROM June 21 to 25, the Associated Advertising Clubs of America will hold their annual convention in Toronto. Not only will new records be established in point of members attending as compared with kindred gatherings on Canadian soil, but there will be borne in upon our people with a renewed forcefulness, the fact that public mediums, whereby the products of the farm, the mill and the factory are brought vividly to their notice, are neither superfluous for their intelligence development nor given to misrepresentation or exaggeration. Relative to the foregoing, subscribers to **The Power House** are invited to take a keener interest in and develop the habit of studying its advertising as well as its editorial, the combination feature producing more immediate and greater returns.

The old order changeth, and although our policy has always been truth and sincerity at any cost, the practice has been far from universal. While appreciating therefore the general advance now being made, we simply reiterate former appeals to our readers to appropriate to themselves the benefits derivable from closely scrutinizing the offerings of those who advertise with us.

UNIFORMITY OF BOILER INSPECTION.

A UNIFORM standard for boiler inspection to govern the whole of Canada, long urged by the departments of the more energetic provinces in this respect, seems at last to be in sight. A conference of inspectors representing all but two provinces is at present in session in Toronto and if the earnestness and good-will of the delegates shown in the preliminary meetings be an indication of possible results, we are sure much needed reform will be accomplished.

The evils of the present agglomeration of standards, easily evident to the average citizen, have been exceedingly troublesome to all concerned with boiler design, construction and operation. A firm in Pittsburgh which had, after some expensive lessons, succeeded in getting their product adapted for Ontario, found different and possibly more troublesome experiences ahead of them on shipping a consignment to British Columbia. In some cases it has been more advantageous to buy boilers for British Columbia in the Western States than in the Eastern Canadian provinces, a line of action contributory usually to much heart-burning and ill-will.

The objects of the conference cannot be accomplished without difficulty on account of the wide variance of the present standards and the diversity of the ideals sought by the different representatives. Nevertheless, while the common standards adopted may not be perfect in the eyes of some, our boilers will be safe, and the educative effect of the conference cannot but raise the general order of boiler inspection throughout the Dominion. It is to be hoped that the success in this will lead to uniform requirements for engineers and firemen and other much needed standards in the engineering profession.

FACTORY ACT AMENDMENT.

AN amendment to the Factory Act in the Province of Ontario seeks to include men who operate hoisting engines within the scope of the requirement of a stationary engineer's operating license. The term "hoisting engines" is rather vague and seems to imply a complete absence of both knowledge and purpose on the part of those responsible for this projected addition to the statutes. Hoisting engines embrace a particularly wide field, some sections of which are on a par with many of our power plant units, and are no doubt considered, at least, as such by their owners in the matter of licensed competency. We presume, however, that it is now sought to include crane equipment, steam shovels, concrete mixers, etc. If this be the case, some concurrent legislation which will discriminate between man and man, and reward higher intelligence and capacity attainment should be provided.

THE OPERATORS' VIEWPOINT

Devoted to brief descriptive article contributions covering ideas and experiences pertaining to power plant practice and operation. We pay for accepted material.

STRESS ON BOLTS OF SPLIT FLY-WHEEL.

By J. R. Brodie.

I NOTICED in a recent issue of your journal a problem propounded by Mr. Westwood regarding the stresses acting on the bolts of a split fly-wheel. As such discussions tend to add to the interest in the paper, I shall endeavor to set forth my theory and a calculation. The data given are as follows:—

Diameter 12 ft., r.p.m. 150, and weight 10 tons. The hub was held intact by four 2½ in. bolts, with an initial stress in each of 1,000 pounds, and the rim was secured by four 2 in. bolts, each under an initial stress of 700 pounds.

The stress in the rim of the fly-wheel is found by the following formula (a):

$$S = \frac{R \times N^2 \times W \times F}{2 \times 3.1416} \text{ where}$$

S=Total rim stress in pounds.
R=Mean radius of fly-wheel in feet.
N=Number of revolutions per minute.
W=Weight of rim in pounds.
F=Constant for centrifugal force of whole rim=.000341.
3.1416=Ratio of circumference to diameter of circle.

The weight of the rim is not given and, for this reason, it is necessary to ascertain its stress per sq. inch.

The weight of a cast-iron rim may be found by formula:

$W = 2 \times 3.1416 \times R \times 3.125$, where
W=Weight of rim.
3.1416=Ratio of circumference to diameter.
3.125=A constant for cast-iron.
R=Mean radius of wheel.

Weight of rim$=2 \times 3.1416 \times 6 \times 3.125$ $=117.813$ pounds.

By formula (a), the total stress in section of rim one inch square and 12 ft. diameter will equal

$$S = \frac{6 \times 22500 \times 117.8 \times .000341}{6.2832}$$

= 863 pounds per sq. in.

The width of the crown and its thickness are not given. Therefore it is necessary to base the calculation for the total weight of the rim upon the assumption that the dimensions are as follows:—Width 18 in., thickness 4 in., or cross sectional area$=18 \times 4=72$ sq. in.

The total stress on the rim in pounds =sectional area in sq. in. $\times$ 863= $72 \times 863=62{,}136$ pounds.

Area of a 2 in. bolt=3.1416 sq. in., and total stress on each bolt=62.136÷4 =15.534 lbs. The initial stress on each rim bolt due to the tightening is 700 lbs.

Now, if the strains on the bolts increase in proportion to the loads they are called upon to carry, the total stress on each bolt is $15{,}534 + 700=16{,}234$ pounds. The stresses on the hub bolts, in my opinion, are very moderate, and are, therefore, not considered.

It was said by "Centrifugal" that the speed of the wheel was too high. The maximum allowable strain in a cast-iron fly-wheel rim is 1,000 pounds per sq. in., which corresponds to a rim velocity of 6,085 ft. per minute, which brings the wheel in question within safe limits. Its rim velocity is 5,655 ft. per minute, while the rim stress is 863 pounds per sq. in.

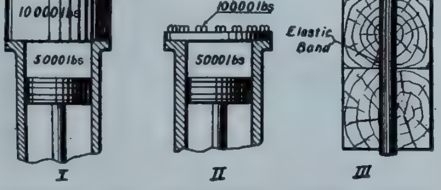
TENSION ON CYLINDER STUDS.

By N. G. Near.

I CANNOT refrain from offering my views on the cylinder cover stud question in which I agree in part with Mr. Rodgers. When steam is turned into a cylinder there must be an increase in tension in the studs, but that increase is very small in proportion to the initial tension produced by tightening the nuts.



TENSION ON CYLINDER COVER STUDS.

This pressure slightly compresses the nut and the cover and there must be some compression also in the cylinder itself. All materials, including cast iron and steel, are elastic, the stud alone being elongated. As soon as steam is turned on, a small part of the initial compression in cylinder and cover will be relieved, with the result that there will be a slight increase in the tension of the cylinder bolts, but, as mentioned before, this increase is practically negligible.

A glance at the two cylinder ends shown will make this clear. Fig. 1 is closed steam-tight by means of a 10,000 pound weight, while the joint of Fig. 2 is made in the usual way with the cover pulled down by a total force of 10,000 pounds. The nature of the pressure at both steam joints is about the same and the pressure per sq. in. of metal against metal would be computed in the same way. The real difference is that one joint is elastic and the other is not. The weight in No. 1 would not have to be increased until the total pressure of the steam exceeded the applied load. The studs, on the other hand, are stretched and the tension is correspondingly increased until the slight compression of the metal of the cylinder is relieved. After this takes place, the pressure of the head against the studs is simply transferred from the cylinder body to the steam and little further increase in tension takes place. The exact amount of the increase in tension, of course, would be hard to measure.

Another illustration is shown in Fig. 3, which consists of two blocks of wood held together by a rubber band to represent the elastic tendency of the studs and a thin sheet of rubber between them to represent the elasticity of the cylinder cover and packing. It will be found that the slightest pull stretches the outer band until the very small compression between the blocks is relieved. Beyond this the blocks will not be separated until a pull is applied equal to the tension of the band.

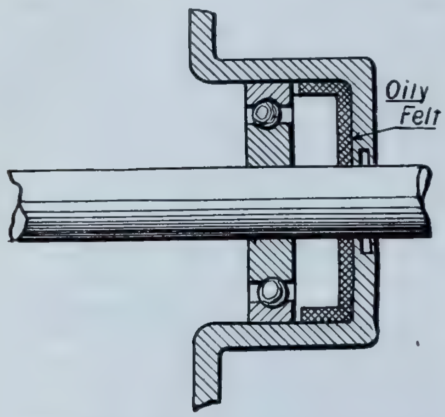
SCHEME FOR CATCHING DIRT IN BALL BEARINGS.

By N. G. Near.

TO keep dirt and grit out of your ball bearings, keep the balls covered with a thin coat of oil sufficient to prevent them rusting, and your principal ball-bearing troubles are eliminated.

Ball bearings are now made for almost every machine where minimum friction is desirable. For shafting transmission they are made particularly strong, rugged and durable. There are many varieties of dirt shields for protecting the balls and races, some of them very effective, but to be absolutely sure that a minimum of dust will filter into the vital parts, it is a good plan to glue felt around the interior of the shield as shown in the sketch herewith and make it moist with oily graphite or other lubricant that will not dry. When a dust particle enters, it will be thrown against this trap by air currents set up by the rotating balls. Thus, whether the bearing is in use or not the dust particles have little chance to get to the surfaces where harm might be done. After several years of use the felt can be rinsed clean with gasoline.



CATCHING DUST IN BALL-BEARINGS.

SOLDERED JOINT QUERY.

By J. N. Ellethorn.

ON page 163, May issue of **The Power House,** a reader wishes to know why soldered joints will not prove satisfactory on steam coil joints. Solder, commonly known as tinsmith's solder, is made from equal quantities by weight of block tin and lead. Again, plumber's solder, which is used to make wiped joints has a larger quantity of lead than tin—usually about three of lead to two of tin by weight.

Steam at 100 pounds gauge pressure has a temperature of 327.625 degrees Fah. Tin melts at a temperature of 444 degs., lead at 614 degs.; half and half melts at 466 degs., and two to one at 475 degs., Fah. In view of the foregoing, it requires no great knowledge to understand that with steam at a high temperature passing through split pipes with soldered breaks, the solder will become very soft and weak. The pressure will soon force the solder apart as the pipe expands at the break, for as the solder becomes heated it looses its power to hold together the two sides of the split.

Even on low pressure steam-pipes a soldered joint is not to be recommended as the expansion of the solder and the iron pipe is altogether different. For example: the linear co-efficient of expansion for iron for each degree increase in temperature is .00000686, for steel pipe .00000599, and for tin .00001,410. Positively no soft soldered joint should be used on a steam pipe. For hot or cold water or any cold gas pipes it is all right if the pressures or temperature changes be not too great, because the tensile strength of solder is away below that of iron.

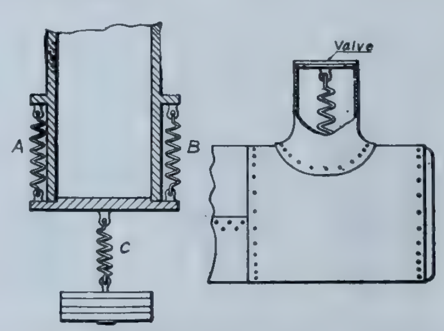
TENSION ON CYLINDER COVER STUDS.

By C. N. Roach.

IN a former issue of your journal, Mr. Rogers proved to the satisfaction of quite a number of readers that if the studs were screwed up with a tension of 1,000 lbs. each and the full steam pressure, amounting to 2,000 pounds, be turned on, the total tension in the studs would be 4,000 lbs. This I do not altogether agree with.

In my opinion there can be no increase of tension on the studs when the steam is admitted to the cylinder. This theory I illustrate with springs as substitutes for studs and the steam pressure. If the cover be held in place with two springs, A and B, each under a tension of 1,000 lbs., the steam pressure can be readily represented by regulating the tension in the spring C.

If the tension in C be raised to 1,000 lbs., the tension on the other springs will still be 1,000 lbs. each. If raised to slightly more than 2,000 lbs., we will begin to note a deflection of A and B, as this will exceed their initial tension. This should corroborate the conclusions of Mr. Jones to the effect that the tension of cylinder studs does not increase until the total steam pressure becomes greater than the tightening up tension in the studs.



TENSION ON CYLINDER COVER STUDS.

Another simple illustration is in the form of a boiler and safety valve. If there were any increase in the tension of the spring it would deflect and steam would blow off before the required pressure was reached. As the steel of the studs is more or less elastic if not seriously overworked, there is no reason why these cannot be cited as parallel cases.

ELECTRICAL FIRES.

By J. E. Noble.

In most cases the chief engineer in large office buildings and factories has charge of the electric wiring for power and light. In hundreds of cases where fires occur, the blame is wrongly placed on such wires, although on the other hand it is a settled fact that many fires are caused by wrong placing or misbehavior of conductors. When proved cases of such fires occur they should be brought to the notice of all chief engineers. The following are a few that have been reported in electro craft from time to time, and although greatly condensed, I think they contain all the information necessary to make them of value to engineers in charge.

(1)—A gas fixture had been removed from a corridor on the upper floor and the wires left lying against a gas pipe. The insulation becoming old, the bare wire came into contact with the pipe, and there being a ground already on the service, an arc was formed. A small hole was burned in the pipe and the gas ignited.

(2)—A 500-volt motor was installed in a small room in a grain elevator. Dust was allowed to accumulate and was ignited by sparks from the brushes. A dust explosion followed.

(3)—Several distribution feeders to lights were run in paper conduits. Some of these conduits were in a channelway adjoining a metal lined air shaft. In fastening the metal lining in place, the nails were driven into the channelway and through the paper conduits containing rubber covered wires. The vibration of the building caused the nails to wear away the insulation of the wires. The arc thus formed set fire to the insulation, to the paper conduits leading to the air shaft, and finally appeared in the attic of the building. Tests made subsequently showed that a 50-ampere fuse in the feeder wires would not blow before a fire was started in the channel-way.

(4)—Cables in a tunnel leading from a large generating station were bunched closely together instead of being properly separated. Ashort circuit occurred on the system and produced such a heavy rush of current in the cables of the tunnel that their insulation melted away, exposing the bare copper. A very vicious arc was formed, and the insulation caught fire, which was in turn communicated to the power house.

(5)—A fire took place in a dwelling where unenclosed plug fuses were placed in the attic. A short circuit occurred at a fixture which blew the fuses, set fire to some wearing apparel and then to the building.

(6)—Old-style insulating joints for combination gas and electric light fixtures allowed gas to escape, which was ignited by small sparks between a grounded wire system and the fixture. The fire was thought to be extinguished, but crept along the insulation of the wires (weatherproof) in a furred wall and broke out later in the attic.

In some of these fires, damage to the extent of $200,000 was done, making it apparent that it pays to look carefully after the wires.

◆

CONCERNING BOILER INSPECTION AND ENGINEERS' CERTIFICATES.

By H. W. Benton.

Why do steam boilers explode? Did you ever ask yourself that question, and have you ever arrived at an explanation that satisfied you? Did you every know, read, or hear tell of a boiler explosion that did not (according to the newspaper) have low water, or an incompetent attendant, as its cause? Of all the boilers that have exploded, few of them were, I believe, operating with low water at the time. All boiler explosions are a result of over pressure: more strain than the shell can stand, hence a rupture of the metal and an explosion.

I believe, however, that low water is a contributing cause to explosions. A boiler may at some time have had low water and, as a result, the exposed sheets below the fire line may have been burnt, thus weakening the plate; yet this same boiler might run months after the sheets were burnt and not show any leak or sign of defect. A defect, nevertheless, exists, and a small crack may start along the sheet and slowly grow in length and depth until some day, when the boiler is steaming under perfectly normal conditions, it will have developed until the plate is too weak for the pressure and fractures. Low water may thus be the cause leading to an explosion, although not the actual condition when it occurs. Again, there may be defects in the longitudinal shell seams that defy attention, that gradually develop until the plate is weaker than the force which it was designed to withstand. We have here another cause for explosion, in which low water does not enter. A boiler explosion is, therefore, a direct result of too much pressure, regardless of whether that pressure was 100 lbs. per sq. in., or only 30 lbs. per sq. in., because from some cause or other the strength of the plate or seam has become weaker than the force it has to withstand, and a burst shell is the inevitable result.

To me there is no mystery about a boiler explosion, except the mystery that there are not more explosions, considering the way some boilers are operated.

Pertinent Example.

I have in mind a return tubular boiler about 40 in. diameter by 12 ft. long, that had a crack about 10 in. long at the furnace sheet. A small hole had been drilled in each end of the crack and then a patch had been fitted on to the bottom of the shell with boiler-patch bolts. The patch got leaking, and the owner did not wish to do anything towards repairing it except feed bran to the boiler.

The fireman was a youth of fair intelligence and had to work for his bread and butter, and although he did not really know, he felt that the bran cure was only adding weight to the millstone that was likely to land the whole outfit at the bottom of Davy Jones' locker. The leakage grew so bad that in the night time the water would leak out enough so that in the morning there was no water in the glass and no way to get any more in except by carrying it in pails and pouring it through the safety-valve. The owner ordered that the boiler be fired up **easy**, mind you, with no sign of water in the glass, and that as soon as there was steam enough to put the injector on, and just fire up enough to run the injector until water showed in the glass.

This plan was followed for several days without any trouble, until eventually the engine was put on before water was in the glass, and the owner said **it will all come right.** At 11 a.m. there was still no water to be seen and the injector had been on full all the morning. Examination showed all tubes to be leaking so badly at the back end that the wonder was there was any water at all in the boiler. A shut-down was ordered, the patch tightened up, the tubes rolled and beaded, and steam gotten up next day as usual. This boiler was installed in a small foundry and machine shop.

Upon another occasion the owner decided to clean out the boiler, so at night he drained all the water out of it. The next day the machine shop man, requiring some power, lit a fire under the empty boiler, and when after some time there was no steam, he looked into the furnace and found the plates red hot.

The foregoing goes to show that it is small wonder that more boilers do not explode, and indicates also, that better boiler inspection laws, together with a better Stationary Engineers' Act are urgently required, so as to eliminate the ignorance and carelessness which lead to boiler explosions.

In the **Hamilton Spectator** a few weeks ago, there appeared an article from the Toronto correspondent stating that the Boiler Inspection Act would likely be widened so as to include Government inspection of every steam boiler in use in Ontario. It stated further that the present Act only provides for the inspection of boilers during construction or repair, but if the present proposed additions became law, all boilers in use in the Province of Ontario will be inspected at least annually, including those in theatres, churches, and public buildings. Dangerous boilers will be condemned, and overtaxed boilers will be penalized down to a pressure allowance that will make them safe. Meantime, a great number of boilers, many of them operated so long that they are a continual menace to life, are allowed to stay on as they are with only the inexpert and perfunctory inspection they occasionally receive under the Factory Inspection Act. To the average person and to the public in general, this article would seem to point out that our operating engineers are a very careless, ignorant, untrustworthy lot, who take great chances on themselves every day with such menaces to life; also that one is taking quite a risk when anywhere near a steam boiler.

That the Province of Ontario needs better protection from boiler explosions is a very great truth, but the widening of the Boiler Inspection Act will do very little towards that end, unless the Stationary Engineers' Act is also made a real Act.

Insurance Company Inspection.

That the great majority of boilers in Ontario need inspection and receive that only under the provisions of the Factory Inspection Act is not altogether true. There are at least three boiler insurance and inspection companies with offices in Toronto, and these concerns have each a number of inspectors continually on the road doing boiler inspection only. The Government could not make a better showing than these men make, because since these people get along with very few losses, it indicates clearly that they know their work, and that the great majority of boilers in our midst are not as risky as we might be led to believe.

There is no doubt, however, that there are many boilers that receive only the Factory Act inspection, and "perfunctory" is the correct word to describe this.

Engineers' Examinations.

The Ontario Government proposes to inspect our boilers and advise if they are safe or not to operate, and under what conditions they shall be operated. They also advise that if our boilers are over 50 h.p. that we must employ a certified engineer to operate them. The examination questions used to ascertain a man's fitness to act and be certified as an engineer are about as much good as questions pertaining to dressmaking would be if applied to test a man's fitness to act as an admiral of the United States navy. The present examination questions for certificates are not even a fair examination for a fireman, to say nothing of an engineer.

I am an advocate for better boiler inspection; it cannot be too strict, or too complete, and I also strongly condemn the present standard of **Stationary Engineers' Certificate** in Ontario, and state positively that unless the Stationery Engineers' Act is improved and made what it should be, any improvement in the Boiler Inspection Act will fall short of its otherwise success. It is a joke, an insult to the intelligence of any real engineer, to be handed an Ontario certificate, as the best the province has to offer.

The Engineers' Act should provide graded certificates, with provision for limiting the power, of which a man could assume charge, and these should consist of first class, second class and third class certificates issued as follows:—

An applicant for examination to state his experience, age, and whether or not he has made a study of steam engineering apart from his daily work.

A candidate to have two years' experience as an oiler or fireman under a certified engineer before being eligible for examination; and to have seven years' experience in all for first class unlimited certificate.

By this system a two-year experience man, even though he be perfect theoretically, could only get a third-class certificate, but by working two years on the third-class certificate he could be examined for second-class. By obtaining this and operating three years on it, or seven years in all, a satisfactory examination would get him a First Class unlimited certificate. Thus, a man all college and no practical experience could not get a fifst-class certificate without the latter, neither could a man with 40 years' practical experience and no technical training get first-class. To be awarded a first-class certificate, a man should have a proper mixture of theory and practical experience, a dual attainment which all right-thinking people agree is essential.

This system would work no hardship on anyone, would be a protection to the public in general, the employers and the engineers themselves, and would raise the standard of engineers generally, while incidentally tending to reduce the number of boiler explosions. Let the third grade certificate acquirement be made fairly easy, but make it a real examination for a first-class certificate. Employers would soon come to acknowledge the certificate as a worthy representative of a man's ability and one to be relied upon, instead of as to-day, **"nothing to go upon at all."**

The Province of Ontario has a Stationary Engineers' Act, the results of which are almost as bad as no law at all, and while better boiler inspection is desired and required, good operating engineers are needed also.

UNIFORM BOILER RULES FOR ALL CANADA.

Representatives from every province in the Dominion, with the exception of Alberta and Manitoba, are meeting at the Parliament Buildings, Toronto, to consider uniform boiler inspection regulations for all Canada. At the present time Alberta, Saskatchewan and Ontario have uniform regulations. British Columbia has regulations that vary somewhat; Manitoba is about to adopt a series, while the other provinces are merely in the "considering" stage.

The conference is of considerable importance to boiler manufacturers, and their representatives will doubtless keep closely in touch with the sessions. If uniform regulations are adopted it will mean that boilers inspected and passed upon during construction can be sent to any part of the Dominion and put into operation without further inspection or suffering any penalty in pressure imposed as a safeguard.

Those attending the conference are J. Peck and R. N. Blackburn, chief inspectors of boilers in the Provinces of British Columbia and Saskatchewan respectively; W. G. Matthewson, of Nova Scotia; P. T. Tobin, inspector of public buildings, Province of Quebec; and D. M. Medcalf, chief boiler inspector, Province of Ontario.

FRACTURED CRANK SHAFT.

After working some considerable time, a large crank shaft fractured through an arm of the crank connected with the high-pressure cylinder. Under shock tests it showed up badly, and its microstructure indicated that it had been overheated. From the indicator diagrams and the weight of the moving parts, the stresses existing in the crank shaft were calculated. The results show that the stresses were not high enough to account for fracture, assuming that the engine had been properly assembled when new. The positions of the bearings, however, had not been happily chosen, which would give rise to greatly increased stresses after wear had taken place, e.g., a wear of 3 mm. on the end—fly-wheel—bearing would just about double the stress on the crank arm which ultimately fractured.

FORCED DRAFT AND ECONOMIZERS.

At a recent meeting of the Chicago Section of the American Society of Mechanical Engineers, "Large Steam Power Plants" was discussed. W. L. Abbott, of the Chicago Commonwealth Edison Co., spoke very strongly in favor of economizers and of mechanical draft, and as this company is one of the largest central stations in the world, and as Mr. Abbott is one of their most prominent engineers, his words are worth noting. In connection with boiler operation, Mr. Abbott stated as follows:

"Air is taken at a normal temperature, heated up to 2,000 or 2,500 deg. and cooled down to 500 or 600 deg. The rest of the heat is used to create a draft—that is, the air is driven up a smokestack, pulling fresh air after it through a fuel bed. To use 20 per cent. of the heat of the fuel merely to push air through the fuel bed is a wasteful process. It is true that the temperature of the water in the boiler is some 400 deg., and cannot cool down the air. The remedy is to use economizer and cool down the furnace gases to the lowest point possible. Abolish smokestacks for the purpose of creating draft. Boilers are being forced 100 per cent. every day, and, with forced draft, from 300 to 400 per cent. Still the limit has not been reached. The boiler can be cut in two, and a half of it forced to 500 per cent. if necessary. The other half could be used as an economizer in two stages if need be, and the gases cooled to the temperature of the feed water. In this way there is a possible saving of 20 per cent."

Such bold statements in favor of economizers and of forced draft are becoming more and more common, and it is undoubtedly due to the fact that economizers have accomplished marvelous fuel savings. Considering this tendency, it seems likely that few draft chimneys will be built in future. Even where chimneys are now used, we frequently find economizers and induced draft being installed.

In Canada the preference for preheating by economizers is very markedly on the increase. A majority of the plants in the lumber, pulp and paper industry are economizer-equipped. At the present writing, the Brompton Pulp and Paper Co. are installing a 1,200-b.h.p. economizer at East Angus, P.Q.; the Belgo-Canadian Pulp and Paper Co., a 750-b.h.p. economizer at Shawinigan Falls, P.Q.; the Toronto Housing Co., a 450-b.h.p. economizer at Toronto; and the Canadian Kodak Co., a 1,200-h.p. economizer at Toronto. The B. F. Sturtevant Co. of Canada, Ltd., of Galt, Ont., is making all three installations.

Instruction Course for Power Plant Operators--II.

By M. L. Smith, B.A.Sc.

Throughout the writer's experience as a teacher, he has been continually confronted with the query: "Can you recommend a text book for power plant employees?" This, on account of specialization of the different branches of the work and the fact that most books published deal with methods of particular localities, is practically impossible. This series of articles is intended to supply the need, to set forth the technical points so that firemen and engineers can understand and apply them, and be thereby assisted in passing the various qualifying examinations.

THE student at this stage should observe that every kind of engine cannot be fully explained, and that limited space allows only to be discussed the foundation types which most clearly show the principles involved. The young engineer should make a point of being present when engines, pumps, etc., are being taken down, and by a willingness to be of service, put himself in the way of learning what there is to know without asking too many questions. A great deal is also to be gained by visiting other plants in spare time, and becoming acquainted with other engineers.

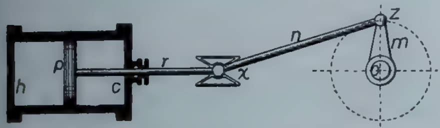


FIG. 5.—FOUR LINK SLIDER CRANK.

Classification of Engines.

Steam engines may be classified in many different ways. The following, however, embraces practically all that are in use at the present time.

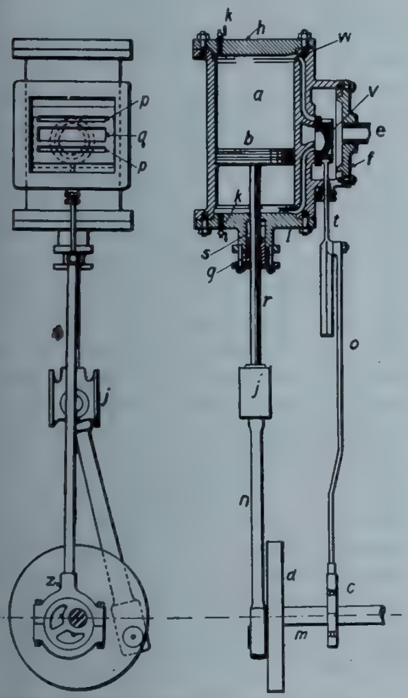

FIG. 6.—THE SIMPLE SLIDE VALVE ENGINE.

(1)—According to number and arrangement of cylinders—Simple, compound, triple, quadruple, duplex, etc.

(2)—According to the type of valve used—Plain slide valve, automatic cutoff, Corliss, etc.

(3)—According to kind of service—Locomotive, marine, stationary, portable, etc.

(4)—According to general method of operation — Reciprocating, oscillating, rotary, turbine, etc.

Definition.—A simple engine is one in which the steam is worked in one stage, and usually in one cylinder. There may be several cylinders, but if each is fed with live steam, that is, steam directly from the boiler, or if each cylinder is supplied with steam at the same pressure, they will form parts of a simple engine. The same engine may belong to all of the above classes, thus a simple engine may be plain slide valve, stationary and reciprocating. All of these classifications except the last are either self explanatory or will be thoroughly explained later in the course.

Definition.—A reciprocating engine is one in which some of the main parts move to and fro. Reciprocating parts are those which move backwards and forwards; thus, the moving parts of an engine are spoken of as reciprocating and rotating.

An oscillating engine cylinder is pivoted at its center so that it rocks about this point instead of having a connecting-rod. This rocking motion also looks after the steam distribution, so that the engines consist simply of a cylinder, piston with rod and crank. They are used mostly for elevators, carriages in lumber mills, etc.

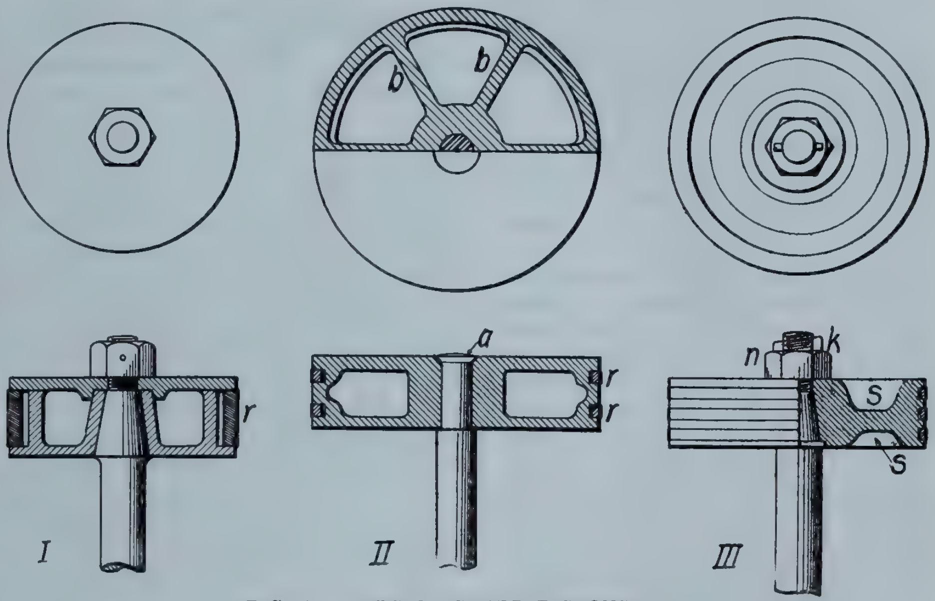

FIG. 7.—TYPES OF SMALL PISTONS.

A rotary engine is one whose main parts rotate or move in a circle. It uses the direct pressure of expanding steam in the same way as a reciprocating engine, and usually consists of sliding vanes in a revolving drum placed eccentrically in a cylinder, or it may have the verolving drum in the center of an oval cylinder.

A turbine is similar to a water wheel in that it makes use of forces of impulse and reaction in which steam takes the place of water.

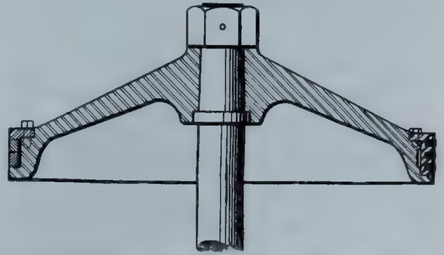

FIG. 8.—LARGE PISTON WITH JUNK RING

It may be said by some that the reciprocating slide-valve engine is going out of use. Nevertheless, it still predominates, and as its working is comparatively easy to understand, and its principles largely underlie all steam engines, it will be carefully explained here.

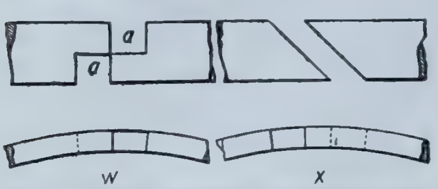

FIG. 9.—SIMPLE FORMS OF PISTON RING JOINTS.

The simplest form of the steam engine is known as the four-link slider crank motion as shown in Fig. 5. It consists primarily of the cylinder (c) in which the steam is expanded, pushing the movable partition or piston (p) ahead of it; thus both the piston and the rod (r) are forced to move in a straight line in one direction. If now the steam which caused this motion be allowed to escape and fresh steam be admitted to the other end of the cylinder, the piston will be forced back to its starting point or will move in a straight line in the opposite direction. This constitutes the reciprocating motion. The link (n) is known as the connecting-rod, because it connects the back and forth motion to the circular motion. Its purpose is to change reciprocating motion at (p) to rotary motion of the shaft (o). The fourth link (m) is called the crank. Its business is to force the end of the connecting-rod to move in a circle.

Construction.

Fig. 6 shows two views of a simple slide-valve engine, the one on the left having the valve removed in order to show the ports. The cylinder (a) is made of cast iron, and is bored straight and smooth. It should be of a slightly harder and closer-grained grade of iron than the piston and should be made of an even thickness to prevent warping. The piston (b) is also cast iron and is turned to a loose fit in the cylinder. Fig. 7 shows several common types of small piston heads, (1) being a built-up piston which is held together by the same nut that fastens the head to the rod. This kind of taper fit is not good, as with both the steam pressure and the tension of the nut it is liable to act like a wedge and burst the head; (2) represents a solid, box type piston shrunk on the rod, which is then riveted over. This is also poor practice and is allowed only on small or cheap work. A very good method is shown in (3) for fitting rod and piston together, except that most men prefer a pin threaded through the nut instead of the key shown. The fault with this piston is that it is difficult to make the cylinder heads (h) and (i), Fig. 6, to fit closely around them, and the clearance space is made unavoidably large.

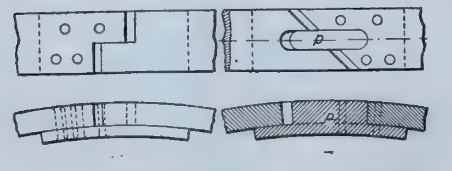

FIG. 10.—IMPROVED FORMS OF PISTON RING JOINTS.

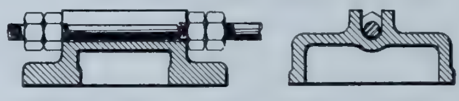
Piston heads are kept steam-tight by means of packing rings fitted into turned grooves. These rings are turned slightly larger than the cylinder bore; an amount equal to about 1-16 inch for each inch of diameter of cylinder being cut out. The ring is compressed to a smaller circle and again turned to fit the cylinder. When in place, it tends to spring out against the cylinder walls and to wear to a perfect steam-tight fit.



SIMPLE FORM OF "D" SLIDE VALVE.

Two of the simplest ways of splitting rings are shown in Fig. 9. The parts (aa) are the portions cut out. It is easily seen that, as a joint, neither of these is very good, as a small amount of steam can leak down one space (a) and up the other. This is prevented by riveting brass plates on the back as shown in Fig. 10. The piston head shown in Fig. 8 is a type much used for high pressures and large cylinders. The cone shape is for the sake of strength. A great advantage is that the packing rings are held in place or are carried by a junk ring which permits of their removal without withdrawing the piston.

At the other end of the piston-rod, Fig. 6, is the cross-head (j) which makes a hinge joint between it and the connecting-rod. This particular type is known as a Corliss cross-head, and its guides as Corliss guides. The length of the connecting-rod should be at least 3½ times that of the crank, and the bearings should be so arranged that this length from center to center does not change with wear. The crank (d) is made up of the crank-arm and crank-shaft (o). In high-speed engines the crank-arm is usually in the form of a flat disk with the crankpin shrunk in, being thereby much more conveniently balanced or counter-weighted than a plain arm.

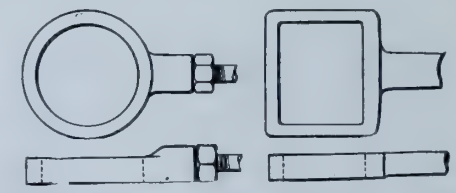


FIG. 12.—TYPES OF VALVE YOKES.

It is particular to notice that the eccentric (e), Fig. 6, is really a small crank whose purpose is to give a reciprocating motion to the valve (v). A simple form of D valve is indicated in Fig. 11, which is intended to show the method of attaching the valve stem (t), Fig. 6. It is desirable to be able to adjust the length of the valve stem, and the valve should be free to adjust itself up and down to accommodate wear. In this case the stem adjustment is by means of nuts. Fig. 12 shows two forms of yokes which fit over bosses on the back of the valve.

It will be observed that the valve seat containing the steam ports (pp) and the exhaust port (q) is made short enough to allow the valve to slide completely over its face, and thus prevent the formation of ridges at the ends of the valve travel. For the same reason the cylinder is bored larger at the ends to form the counter-bore (w). The edge of this counter-bore should come to the center of the outside piston ring when the engine is at either end of its stroke. The whole valve mechanism, including eccentric and strap, eccentric rod, valve-stem, valve, etc., is known as the valve gear. The front end of the engine is called the crank end and the rear the head end. The length of the movement of the piston in one direction is called the stroke and the chamber from which the steam is distributed to the cylinder is known as the steam-chest.

Tube Failures.—It was the custom at one time to ascribe all tube failures in water-tube boilers to bad workmanship in the welding of the tubes. Since the introduction of seamless tubes this excuse is no longer available, and other causes have been sought and found. An examination of a large mass of material relating to tube failures has proved that the true cause of these failures is most usually impure feed water, either alone or in conjunction with imperfect combustion, due to badly designed grates and combustion space. Too often the baffling of the gases, with the introduction of secondary air, occasions a completion of the combustion process and great increase of temperature, after the gases have passed up to the boiler tubes —hence overheating occurs, especially where impure feed water is being used and the tubes contain deposits of scale. The remedy for tube failures is, therefore, to use chiefly pure water from condensers freed from oil, in conjunction with ordinary feed-water supply, after chemical treatment to free it from the scale-forming salts.

Series of Practical Questions and Answers for Engineers

Every care is being taken to include only pertinent, practical questions, and give same direct reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division of decimals, will be found a most useful companion study, and should not be overlooked.

BOILER QUESTIONS FOR ENGINEERS' EXAMINATIONS.

Question.—In taking charge of an engine and boiler plant, what would be the proper way to proceed?

Answer.—Observe the water level, trying gauge cocks and blowing out glass if necessary. Note steam pressure; try injectors or see that feed pumps are working properly. Feel all important bearings and see that lubricating apparatus is in good order. It is the duty of the engineer going off watch to turn the plant over acceptably to the man coming on.

* * *

Question.—What is a good way of banking a fire?

Answer.—Push the live coals back against the bridge wall so as to leave the forward part of the grate covered with ashes. Cover the fire with a fairly thick layer of fine coal and some ashes. Leave the damper open a very little to prevent the collection of gas and possible explosion. When starting up it is simply necessary to pull the fire evenly forward and shovel on fresh coal.

* * *

Question.—How are pipes and tubes measured?

Answer.—Pipes are measured by the inside diameter and tubes are gauged by the outside diameter.

* * *

Question.—What points should be observed in connecting up a water column to a boiler?

Answer.—Connecting pipes should not be smaller than one inch in diameter and preferably of extra heavy pipe or drawn brass tubing. Bottom pipe should be connected with a ground joint brass union so that the bottom of the water glass or the bottom gauge cock will be at least 1½ inches above the top row of tubes. Plugged tees should be used instead of elbows to allow cleaning. The bottom pipe should be level and fitted with a gate valve blow off.

* * *

Question.—Is there any difference in the speed with which water and steam will escape from the same boiler?

Answer.—Yes. Volume for volume, the steam will escape about twenty times as fast as the water.

* * *

Question.—What is the effect of an accumulation of scale and soot on a boiler?

Answer.—A coating of soot or scale is a bad conductor of heat, hence heat is prevented from getting to the water and to get the same amount of steam from the boiler, extra coal is needed thus:—1-16 inch of scale necessitates 15 per cent. extra fuel; ⅛ inch of scale necessitates 32 per cent. extra fuel; ¼ inch of scale necessitates 66 per cent. extra fuel; ½ inch of scale necessitates 150 per cent. extra fuel.

* * *

Question.—How would the heating surface of a return tubular boiler be determined?

Answer.—Multiply the inside circumference of one tube in inches by its length in inches and by the number of tubes. Divide this by 144, which will give the number of square feet of heating surface supplied by the tubes. From the area of one end subtract the combined area of the tube ends all in inches and divide by 144. This will give the heating surface of the tube sheet. Multiply two-thirds of the circumference of the shell in inches by its length in inches and divide by 144. The result will be the heating surface of the shell. The sum of these three will be the total heating surface of the boiler in square feet.

* * *

Question.—In examining the interior of a boiler what are some of the defects to be looked for?

Answer.—(a) Loose and broken stays and loose rivets, (b) effects of corrosion such as pitting, grooves, etc.; (c) Fractured, burned and laminated plates; (d) Defective blow off connections; (e) Thin and defective tubes, etc.

* * *

Question.—What should be the chief aim in firing?
